

Where Do They Really Go?

*Bay Area Private School College Placement — By the
Numbers*

CHAPTERS 1–7

April 2026

All data sourced from official school publications, UC InfoCenter, and public competition results. Verified against original sources. See Appendix A for full methodology.

Chapter 1: What the Brochure Doesn't Say

Who this chapter is for: T1 readers — parents who are new to college placement data and just starting to wonder what their school's numbers actually mean. No prior knowledge assumed.

School placement data is real. It is also structurally misleading. Learning to read it — really read it — is the most important skill a Bay Area parent can develop. This chapter teaches that skill, using one school's data to show how every school's numbers work.

You are sitting at your kitchen table on a Sunday night, laptop open, a glass of something next to it. Your kid is in third grade at a well-regarded Bay Area private school. You just came back from a dinner where another parent mentioned — casually, as if discussing the weather — that their school sends twenty-eight kids to Stanford. Twenty-eight. You pull up your school's college placement page. The list is long. Harvard, Yale, Princeton, Stanford, MIT. Names you recognize, names that feel like destinations. The page is designed to impress, and it works.

Then you do what every data-literate Bay Area parent eventually does: you start counting. You start asking questions the page doesn't answer. And that is where this chapter begins.

The Headline Numbers

Let's use a real school. Sacred Heart Preparatory in Atherton publishes one of the most detailed college placement datasets of any Bay Area private school — five years of data (2021-2025), with applied, accepted, and enrolled counts for each college. [A]

Here is what the headline looks like:

Year	Class Size	Ivy+ Enrolled	Ivy+ Rate
2021	155	28	18.1%
2022	155	25	16.1%
2023	171	28	16.4%
2024	149	30	20.1%
2025	160	22	13.8%
5-yr avg	158	26.6	16.8%

Ivy+ here means the eight Ivies plus Stanford, MIT, Caltech, Duke, UChicago, Northwestern, Johns Hopkins, and Georgetown — the schools most parents are mentally benchmarking against. [E]

Those are strong numbers. Nearly one in six graduates enrolling at an Ivy+ school, every year, for five years. Twenty-eight students enrolled at Stanford over that period. If you are a parent reading this page, your takeaway is clear: this school gets kids into top colleges.

That takeaway is not wrong. But it is incomplete.

The First Crack: Athletes

Sacred Heart is unusual in one important way: it publishes annual athlete commitment lists. Most schools don't. This means SHP is the only school in our dataset where we can decompose Ivy+ placements into recruited athletes and everyone else. [A]

****Figure 1.1:**** SHP five-year Ivy+ placements decomposed by athlete recruitment status. Water polo and lacrosse account for 36 of 50 athlete-to-Ivy+ commits.

Here is the same table, with the athlete layer visible:

Year	Class Size	Total Ivy+	Athletes to Ivy+	Non-Athlete Ivy+	Headline Rate	Non-Athlete Rate
2021	155	28	3	25	18.1%	16.1%
2022	155	25	20	5	16.1%	3.2%
2023	171	28	8	20	16.4%	11.7%
2024	149	30	13	17	20.1%	11.4%
2025	160	22	6	16	13.8%	10.0%
5-yr	790	133	50	83	16.8%	10.5%

The five-year headline Ivy+ rate is 16.8%. Remove recruited athletes, and it drops to 10.5%. That is a six-percentage-point gap — more than a third of the headline number.

Two sports dominate this pipeline. Water polo sent 22 athletes to Ivy+ schools over five years — including 10 to Stanford alone. Lacrosse sent 14, primarily to Duke, Georgetown, Princeton, and Brown. Together, these two sports account for 72% of all athlete-to-Ivy+ commits from SHP. [A]

Consider this micro-case. A family we'll call the Chens moved to the Peninsula from the South Bay when their daughter was in fifth grade. They chose SHP partly because of the college placement numbers — nearly 17% Ivy+ rate, Stanford as the top destination. Their daughter is a strong student, plays violin, does robotics. She does not play water polo or lacrosse. The Chens' realistic baseline is not 16.8%. It is closer to 10.5%. That is still a strong number. But it is a different number than the one that influenced their school choice.

The Stanford Question

Stanford deserves its own section because it is the number every Peninsula parent looks at first.

Year	Applied from SHP	Accepted	Enrolled	Athlete Commits to Stanford
2021	29	5	5	0
2022	23	8	8	8
2023	24	7	5	1
2024	20	3	3	0
2025	26	7	7	1

Look at 2022. Eight students from SHP enrolled at Stanford. All eight had athletic commitments — seven in water polo, one in lacrosse. The non-athlete Stanford enrollment that year was zero. [A]

In 2021, by contrast, five students enrolled at Stanford with zero identified athletic commits. In 2025, seven enrolled, of whom one was a recruited water polo player — leaving six non-athlete admits.

The five-year total: 28 SHP graduates enrolled at Stanford. Of those, 10 were recruited athletes (all in water polo or lacrosse). The non-athlete count is 18 — an average of 3.6 per year from a class of 158.

That is a 2.3% non-athlete Stanford enrollment rate. Real, but very different from the impression created by "28 students went to Stanford."

The Second Crack: Applied, Accepted, Enrolled

Most school placement pages list colleges where graduates "matriculated" or "enrolled." Some list where graduates were "accepted." A few — SHP among them — publish all three: applied, accepted, and enrolled. [A]

These are different numbers, and the gaps between them tell you different things.

****Figure 1.2:**** The funnel from application to enrollment at Stanford for SHP students (2021-2025 combined). Nearly three-quarters of SHP applicants to Stanford are not accepted.

A school that reports "accepted" will show a bigger list than one that reports "enrolled." A school that reports a cumulative five-year list without specifying years will show the biggest list of all. When you see a college placement page, the first question to ask is: what is this page actually counting? [E]

Consider a second micro-case. A family we'll call the Patels are touring a private school. The admissions team shows a slide: "Our graduates have been accepted to Harvard, Stanford, MIT, Yale..." The list is long and impressive. But "have been accepted to" over an unspecified time window could mean two students across ten years. Without knowing the denominator (class size), the numerator (how many), and the timeframe (which years), the list is atmosphere, not data. The Patels, both engineers, start asking those questions. The admissions officer has not been asked them before.

The Third Crack: Year-to-Year Volatility

College placement is not a stable output. It varies significantly from year to year, driven by the specific students in each graduating class, admissions office priorities that shift annually, and randomness that no school can control. [E]

SHP's data makes this visible:

- In 2024, SHP's Ivy+ rate was 20.1% — the highest in five years.
- In 2025, it dropped to 13.8% — the lowest in five years.
- The non-athlete Ivy+ rate swung from 16.1% in 2021 to 3.2% in 2022 to 11.7% in 2023.

The 2022 anomaly is worth understanding. That year, SHP had 40 athletes commit to play college sports — the highest of any year in the dataset. Twenty of them went to Ivy+ schools. The class of 2022 happened to have an extraordinarily deep water polo cohort, with players committed to Stanford, Princeton, and Brown. That single-sport pipeline produced a year where nearly all Ivy+ placements were athletes.

No parent looking at SHP's cumulative five-year numbers would see this. The five-year average smooths it into a clean 16.8%. But if your child graduated in 2022 and was not a recruited athlete, the Ivy+ rate that mattered to your family was 3.2%, not 16.8%.

The lesson is not that 2022 was a bad year. It is that any single year's data can be dominated by factors unrelated to the school's academic program. A school with a strong water polo pipeline will have years where the Ivy+ count spikes because of athletic recruitment. A school with a small graduating class will have years where a handful of exceptional students drive the numbers up — and years where they don't. [E]

This is why this guidebook uses five-year windows wherever possible, and why Chapter 2 teaches you to ask for multi-year data when a school shows you a single year.

What This Chapter Is Not Saying

This chapter is not saying schools are lying. SHP publishes more data than almost any peer school. The numbers on their placement page are accurate. [E]

This chapter is not saying athlete recruitment is unfair, illegitimate, or bad. Recruited athletes earned their spots through years of training. Families who invest in athletics have made a strategic choice, and it pays off in admissions. That is data, not a judgment.

This chapter is not saying SHP is a bad school. SHP's non-athlete Ivy+ rate of 10.5% is strong by any standard. The school's willingness to publish granular data is a mark of confidence.

What this chapter is saying: **the headline number on any school's placement page is a composite.** It blends athletes and non-athletes, single-year spikes and multi-year averages, acceptances and enrollments. Once you learn to see the structure inside the composite, you can read any school's data accurately — and make better decisions for your family.

What This Means for Your Family

A third micro-case. A family we'll call the Nguyens have a first grader at a Bay Area private school. They came to the school partly because of its placement record. After reading this chapter, they feel something between deflated and relieved. The numbers are still good — just different from what they assumed.

Here is what changes when you see the structure:

You stop comparing headline numbers across schools. One school's "18% Ivy+ rate" might include 40% athletes. Another school's "12% Ivy+ rate" might include zero athletes. The second school may actually be placing more non-athlete students into Ivy+ colleges. You cannot compare without decomposing.

You start asking better questions at school tours. Not "where do your graduates go?" but "how many of your Ivy+ placements last year were recruited athletes?" and "can you share year-by-year data, not just cumulative?" Most admissions teams have never been asked. Some will answer. Some won't. Both responses are informative. [E]

You recalibrate your expectations. If your child is not a recruited athlete — and statistically, most children are not — the number that matters is the non-athlete placement rate. At SHP, that is 10.5% over five years. At schools that don't publish athlete data, you will need to estimate. Chapter 3 shows you how.

You gain perspective. A 10% non-athlete Ivy+ rate at a private school is real. It means roughly one in ten non-athlete graduates enrolls at a top-16 university. That is meaningfully higher than the national average. It is also not 17%, and the difference matters when you are making a \$50,000-per-year decision.

****Figure 1.3:**** Decision tree for reading any school's college placement page. Start at the top; follow the branches to understand what the numbers actually mean for a non-athlete family.

Quick Reference

What you see	What to ask	Why it matters
"28 students went to Stanford"	How many were recruited athletes?	At SHP, 10 of 28 were. The non-athlete number is 18 over 5 years.
"18% Ivy+ rate"	Is that for one year or multiple? Athletes included?	SHP's 16.8% headline drops to 10.5% without athletes.
"Our graduates attend Harvard, Yale, Stanford..."	How many per year? Enrolled or accepted?	A cumulative list over 10 years tells you very little about this year's class.
Strong single-year numbers	What were the other years?	SHP's non-athlete rate ranged from 3.2% to 16.1% in the same five-year window.
No athlete data published	Does the school have strong sports pipelines?	Schools with D1 water polo, lacrosse, or rowing often have athlete-heavy Ivy+ counts.
Applied vs. accepted vs. enrolled	Which number is on the page?	SHP: 122 applied to Stanford over 5 years, 30 accepted, 28 enrolled. Each tells a different story.

Chapter Evidence Note

This chapter relies primarily on **Tier A** (official school data) and **Tier E** (author synthesis) evidence.

Tier A claims: SHP class sizes, Ivy+ enrollment counts, athlete commitment lists, Stanford applied/accepted/enrolled numbers — all from SHP's published school profiles, college placement documents, and athlete commitment pages (2021-2025). These are official school publications and are verified against multiple source documents.

Tier E claims: The interpretation that headline placement data is "structurally misleading," the non-athlete rate calculation methodology, the recommendation to decompose athlete vs. non-athlete placements, and the year-to-year volatility analysis — these are author synthesis based on the Tier A data. The decomposition math is straightforward, but the framing and recommendations reflect the author's judgment about what matters for non-athlete families.

All school data in this chapter is from official SHP publications covering graduating classes 2021-2025. Athlete commitment data is from SHP's published annual athlete pages. Class sizes are from SHP school profile PDFs filed with college counseling offices. Before making decisions based on specific numbers, verify with current school publications.

Chapter 2: How to Read School Placement Data

Who this chapter is for: T1-T2 readers — parents who want to do their own research on college placement. Once you know the four source types and what each one hides, you can evaluate any school's data yourself.

Every Bay Area private school publishes college placement data. None of them publish it the same way. Learning to navigate the differences — and to cross-check one source against another — is the skill that separates a parent who *consumes* school marketing from a parent who *evaluates* it. This chapter gives you the taxonomy.

You are trying to compare two schools. Menlo School's profile says 30 graduates enrolled at Stanford over three years. [A] Harker's college counseling page says 34 graduates enrolled at Stanford — also over three years. [A] The numbers look close. You could conclude these schools have similar Stanford placement rates.

But Menlo's "three years" means the classes of 2023-2025. Harker's "three years" means the classes of 2023-2025. So far so good. Now look deeper. Menlo has class sizes of roughly 143. Harker's upper school graduates roughly 280 per year. [A] Thirty Stanford enrollees from 429 Menlo graduates (three classes) is a 7.0% rate. Thirty-four Stanford enrollees from roughly 840 Harker graduates is 4.0%. The school with the higher number has the lower rate. [E]

And that is the easy comparison. At least both schools report enrolled counts over a defined three-year window. What about Nueva, which reports Stanford in a tier — "10 or more" graduates over four years — without an exact count? [A] Or Castilleja, which lists Stanford on its college placement page but publishes no count at all — just the school name, indicating at least one graduate matriculated? [A]

Same question — "how many kids go to Stanford?" — four completely different answer formats. This chapter teaches you how to decode all of them.

The Four Source Types

There are exactly four types of publicly available data sources for Bay Area private school college placement. Each has a specific format, a specific strength, and a specific blind spot. Understanding all four turns you from a passive reader of school websites into an active researcher.

****Figure 2.1:**** The four public data source types for college placement research. Each has distinct strengths and limitations — no single source gives you the complete picture.

Source 1: School Profile PDFs

What they are. Every college-preparatory school creates a "School Profile" — a standardized document sent to college admissions offices alongside student applications. It follows a loose NACAC (National Association for College Admission Counseling) format and typically includes class size, GPA distribution, test score ranges, AP/honors course offerings, and a college matriculation list. [A]

Where to find them. Most schools post their current profile on their college counseling page.

Search: `site:{school-domain} "school profile" filetype:pdf` OR `site:{school-domain} "college counseling"`. Some schools host on Issuu — try

`site:issuu.com "{school name}" school profile`. Older profiles sometimes disappear when new ones go up; download them when you find them. [E]

What they tell you. The matriculation list is the core data. Some schools go further. Sacred Heart Preparatory publishes applied, accepted, *and* enrolled counts for each college across five individual years — the most granular format in our dataset. [A] Others publish less:

School	Format	What You See	What You Don't
SHP	5 individual years, applied/accepted/enrolled per college	Full funnel, year-by-year trends	Nothing — this is the gold standard
Menlo	3-year rolling window, enrolled only	College list with counts	Per-year breakdown; which year each student graduated
Nueva	4-year aggregate, tiered ("10+", "5+", "1+")	Minimum threshold per college	Exact counts — "10 or more" could be 10 or 25
Castilleja	Single-year, presence only (bold = enrolled)	Which colleges, enrolled vs. accepted	No counts at all — you know direction, not magnitude
Harker	3-year combined, enrolled counts	Total count per college	Per-year breakdown
Pinewood	4-year aggregate, asterisk for 2+	College list with minimum counts	Exact counts for most colleges

[A] — all format details from published school profiles in our database.

What they hide. The school controls what goes into this document. Multi-year combined lists prevent you from seeing year-to-year trends. Tiered reporting ("10 or more") gives you a floor, not a ceiling. Presence-only lists tell you a college appears but not how many students went there. These are not errors — they are design choices that favor the school's narrative.

The key question to ask yourself: *What is this list actually counting — enrolled, accepted, or applied? Over how many years? With or without exact counts?*

Source 2: UC InfoCenter

What it is. The University of California publishes admission data for every feeder high school — public and private — going back over 30 years. It is free, official, and searchable. [A]

Where to find it. Go to the UC Information Center (universityofcalifornia.edu/about-us/information-center) and use the admissions-by-source-school tool. Select a school, select a year range, and download. The data includes applicants, admits, and enrollees broken down by ethnicity. [A]

What it tells you that nothing else does. Three things:

1. **The full funnel.** For UC admissions, you get applied, admitted, and enrolled — the same granularity that only SHP provides for private colleges. You can calculate real yield rates and admit rates from any school to any UC campus.

2. **Thirty-year trends.** You can track a school's UC placement trajectory over decades. Is Harker sending more students to UC Berkeley than it did ten years ago? The data answers that question directly.
3. **Ethnicity breakdowns.** This is the only public source that shows demographic composition of applicants and admits from a specific school. For Harker in 2024: 120 of 187 UC applicants were Asian (64%). [A] No school profile, no aggregator, no other source gives you this level of demographic detail.

What it doesn't tell you. UC data covers the UC system only. It tells you nothing about Stanford, MIT, the Ivies, or any other private university. A school that sends most of its graduates to private colleges might look mediocre in UC data. A school that sends most of its graduates to UCs might look excellent. UC InfoCenter is the best single data source for what it covers, but what it covers is one system.

The key question to ask yourself: *Am I looking at UC performance specifically, or am I using it as a proxy for overall placement quality? Those are different questions.*

Source 3: Athlete Commit Pages

What they are. Some schools publish annual "signing day" or "athlete commitment" pages listing every student who committed to play a sport in college. These pages typically include the student's name, sport, and destination college. [A]

Where to find them. Search: `site:{school-domain} "signing day" OR "committed" OR "student athletes" OR "athletic commitments"`. Some schools post on social media only. SHP publishes annual pages with names, sports, and colleges — the most complete athlete data we have found for any Bay Area private school. [A]

Why they matter. Chapter 1 showed that at SHP, 50 of 133 Ivy+ placements over five years (38%) were recruited athletes. [A] Without the athlete commit pages, you would never know this. The headline Ivy+ rate would look like 16.8%; the non-athlete rate is actually 10.5%. This is the single largest adjustment factor in college placement data, and only athlete commit pages let you calculate it.

Who publishes them. Very few schools. Of the eight private schools in our dataset, only SHP publishes complete annual athlete commit lists. This means for most schools, you cannot decompose athlete vs. non-athlete placements from public data. You can estimate — Chapter 3 covers how — but you cannot confirm.

The key question to ask yourself: *Does this school have strong D1 sports pipelines? If so, what share of the headline Ivy+ number might be recruited athletes?*

Source 4: Aggregators

What they are. Third-party sites that compile and rank school data. The three most relevant for Bay Area parents:

- **Niche** (niche.com): Uses National Student Clearinghouse data to show the top colleges where graduates actually enroll. This is the only independent source that verifies enrollment (not self-reported by schools). It also provides overall school ratings, parent reviews, and demographic data. [A — Niche methodology is publicly documented]
- **PrepReview** (prepreview.com): Calculates an "Elite College Placement Index" (ECPI) based on what share of a school's graduates enroll at top-25 national universities. Provides a standardized comparison metric across schools. [C]
- **Chicardgo School** (chicardgoschool.com): Tracks feeder school percentages — what fraction of a college's incoming class comes from each school. Useful for identifying pipeline relationships between specific high schools and colleges. [C]

What they get right. Aggregators solve the comparison problem. When every school publishes data differently, a third party that normalizes the data across a standard framework lets you compare apples to apples. Niche's NSC data is particularly valuable because it is enrollment-verified, not school-reported.

What they get wrong. Methodology is often opaque or delayed. PrepReview's ECPI relies on school-reported data and may use different year windows than the school's own profile. Chicardgo School's feeder percentages are derived from various sources with varying freshness. Rankings invite false precision — the difference between the #3 and #7 school in a metro area is rarely meaningful. [E]

The key question to ask yourself: *Is this aggregator giving me a new data point I can't get elsewhere, or is it repackaging the same school-reported data with a ranking veneer?*

Cross-Validation: How to Check One Source Against Another

A single source tells a story. Two sources tell you whether the story is accurate. The cross-validation technique is simple: find the same data point in two different sources and compare.

Consider a micro-case. A family we'll call the Lees are looking at Harker. The school's college counseling page lists 34 Stanford enrollees over three years (2023-2025). [A] The Lees pull up UC InfoCenter data for Harker. In the same period, 187 Harker students applied to UCs in 2024 alone, of whom 120 were Asian. [A] The UC data doesn't mention Stanford — wrong system — but it confirms the school's approximate class size and demographic composition. The Lees check Niche, which shows Harker's top enrolled colleges. Stanford appears on the Niche list, consistent with the school's claim. [C]

No single check proves anything. But when school-published data, UC InfoCenter demographics, and Niche enrollment data all paint a consistent picture, you can trust the contours. When they diverge — if a school claims strong Stanford placement but Niche doesn't show Stanford in the top enrolled colleges — you have a question worth asking.

****Figure 2.2:**** The cross-validation workflow. Start with the school's own data, then check each element against an independent source. Consistency builds confidence; divergence surfaces questions.

Data Quality Pitfalls

Every school makes choices about how to present its data. These choices are not lies, but they shape what you see. Here are the five most common formats that obscure the underlying signal — all drawn from real schools in our dataset.

Pitfall 1: Multi-Year Combined Lists

The pattern. Harker's college counseling page lists "Classes of 2023-2025" as a single combined list. Menlo's school profile reports three-year rolling windows (Classes 2023-2025 in the current profile, Classes 2021-2023 in the previous one). [A]

Why it matters. A combined list prevents you from seeing trends. Did Harker send more students to Stanford in 2025 than 2023? You cannot tell. Menlo's overlapping windows create a different problem: some students appear in two consecutive profiles. A student from the Class of 2023 appears in both the 2022-23 profile and the 2023-24 profile window. If you are counting across profiles, you risk double-counting. [E]

What to do. For combined-list schools, divide the total count by the number of years to get a rough per-year average. For overlapping windows, never add counts from two consecutive profiles — they share graduating classes.

Pitfall 2: Tiered Reporting

The pattern. Nueva's school profile uses tiers: "10 or more," "5 or more," and "1 or more." Stanford appears in the "10 or more" tier for both the 2020-2023 and 2021-2024 windows. [A]

Why it matters. "10 or more" is a floor, not a ceiling. It could be 10. It could be 22. You have no way to know. For a school with graduating classes of roughly 110 students, the difference between 10 and 22 Stanford enrollees over four years is the difference between a 2.3% rate and a 5.0% rate. [E]

What to do. Treat tiered numbers as minimums. When comparing Nueva to a school that publishes exact counts, use the floor value — and note the uncertainty.

Pitfall 3: Presence-Only Lists

The pattern. Castilleja's school profile lists colleges where graduates matriculated, with bold indicating enrollment and non-bold indicating acceptance. But there are no counts. Stanford appears (bold), meaning at least one Castilleja graduate enrolled. [A]

Why it matters. "At least one" from a class of 51 tells you the school has *a* Stanford pipeline. It does not tell you whether 1 or 8 students went. For a parent comparing Castilleja to SHP (which reports exact counts), the data is incommensurable — you cannot produce a meaningful rate comparison. [E]

What to do. Presence-only lists answer a binary question: does this school place students at this college? They do not answer the rate question. Supplement with UC InfoCenter data (which gives you exact counts for UC schools) and Niche data (which gives rough enrollment rankings).

Pitfall 4: Overlapping Windows That Double-Count

The pattern. Menlo publishes a new school profile each academic year with a three-year rolling window. The 2022-23 profile covers Classes of 2020-2022. The 2023-24 profile covers Classes of 2021-2023. The 2025-26 profile covers Classes of 2023-2025. [A]

The Class of 2023 appears in all three profiles. If you naively add Menlo's Stanford counts across profiles — 23 (from 2020-2022) + 23 (from 2021-2023) + 30 (from 2023-2025) = 76 — you have counted the Class of 2023's Stanford enrollees three times. [E]

Why it matters. Rolling windows are standard practice — many schools do this. The problem arises only when a parent (or an aggregator) treats each profile as an independent data set.

What to do. When a school publishes rolling windows, use only the most recent profile for current data. To build a time series, you need to do subtraction: if the 2021-2023 window shows 23 Stanford enrollees and the 2023-2025 window shows 30, and both include the Class of 2023, you cannot isolate the Class of 2023's contribution without additional data.

Pitfall 5: Metric Confusion (Applied vs. Accepted vs. Enrolled)

The pattern. SHP publishes all three metrics. Most schools publish only one — usually enrolled. But some school websites use ambiguous language: "Our graduates have been accepted to..." or "Colleges our students attend include..." [A/E]

Why it matters. Chapter 1 showed SHP's Stanford funnel: 122 applied, 30 accepted, 28 enrolled over five years. [A] A school that publishes "accepted" numbers will show a list roughly 25% larger than one that publishes "enrolled." A school that publishes "applied" will show a list 4x larger. If one school reports acceptances and another reports enrollments, you are comparing numbers that measure fundamentally different things.

What to do. Before reading any college list, identify which metric it uses. If the page says "attended," "matriculated," or "enrolled" — you are looking at final decisions. If it says "accepted to" or "admitted to" — the real number is lower. If the language is unclear, assume the school chose the most favorable framing.

A Second Micro-Case: The Careful Researcher

A family we'll call the Wangs have a sixth grader at Crystal Springs Uplands. They want to understand the school's college placement track record before committing to upper school. Here is what they find:

Crystal Springs publishes a four-year aggregate list (Classes 2022-2025) with no per-college counts — presence only. [A] That tells them *which* colleges but not *how many*. They check UC InfoCenter: in 2024, 66 Crystal Springs students applied to UCs, 42 were admitted, 9 enrolled. [A] That gives them a UC yield number (21% of admits enroll) but says nothing about Stanford or the Ivies. They check Niche, which shows the top enrolled colleges — useful for ranking but without raw counts.

The Wangs realize they have three data sources, and none of them answers the specific question "what percentage of Crystal Springs graduates enroll at Ivy+ schools?" directly. But together, the sources constrain the answer. UC InfoCenter shows roughly 9-11 students per year enrolling at a

UC from a class of about 90. [A] The school profile's presence list shows Stanford, Harvard, MIT, and Penn appearing. [A] Niche's rankings confirm UC presence but don't show heavy Ivy representation.

The Wangs' conclusion: Crystal Springs places solidly at UCs, with occasional Ivy+ placements. They cannot calculate a precise rate. That is the honest answer — and it is more useful than a false-precision number from a single source.

The Five Questions to Ask Any School

When you visit a school, tour the campus, or meet with the college counseling office, these five questions will tell you whether the school's data is transparent or decorative. Most admissions teams have never been asked these questions. The answers — or the inability to answer — are both informative. [E]

1. **"How many students from last year's graduating class enrolled at [specific college]?"** Not "attend" (ambiguous). Not "were accepted to" (inflated). Enrolled. A specific college. One year. If the counselor answers with a multi-year combined number or redirects to the website, that is a data point.
2. **"What is the graduating class size?"** You need the denominator. Twenty Stanford enrollees from a class of 150 is different from twenty out of 280. Most profiles include this, but not all counselors mention it in tours.
3. **"Of your Ivy+ placements last year, how many were recruited athletes?"** This is the question from Chapter 1. Most counselors will not have this number ready. Some will answer. The ones who answer honestly will earn your trust.
4. **"Can you share year-by-year data, not just a cumulative list?"** A school that shows five individual years is more transparent than one that shows a five-year combined list. The combined list smooths over year-to-year volatility. Ask for the granular version.
5. **"Where can I download the current School Profile PDF?"** If the school makes it easy to find, that is a good sign. If you have to request it, that is a different kind of signal. The School Profile is the document sent to colleges — there is no reason it should be hidden from parents.

****Figure 2.3:**** The five-question transparency test. The number of clear, specific answers you receive from a school's college counseling office tells you how much to trust their published data — and how much to rely on independent sources instead.

What This Chapter Is Not Saying

This chapter is not saying schools that publish less data are hiding something nefarious. Small schools like Castilleja (class of 51) and Pinewood (class of 44-54) have legitimate privacy concerns — publishing exact per-college counts could identify individual students. [E]

This chapter is not saying aggregator data is unreliable. Niche's National Student Clearinghouse data is independently verified enrollment data — that is better than most school-reported numbers. The limitation is coverage and timeliness, not accuracy.

This chapter is not saying you need all four source types for every school. UC InfoCenter alone, used well, gives you more actionable data about a school's college placement trajectory than most school websites provide.

What this chapter is saying: **the format of the data shapes what you can learn from it.** A school that publishes per-year enrolled counts with class sizes gives you a rate. A school that publishes a multi-year combined list without counts gives you an impression. Both are data. They are not the same kind of data. Knowing the difference is the skill.

Quick Reference

Source Type	Where to Find	What It Shows	What It Hides	Best For
School Profile PDF	School's college counseling page; search filetype:pdf "school profile"	Class size, test scores, college list (format varies wildly)	Year-to-year detail (if combined); exact counts (if tiered/presence-only)	The official starting point for any school
UC InfoCenter	universityofcalifornia.edu/information-center	Applied, admitted, enrolled at each UC; ethnicity breakdown; 30-year history	Nothing about non-UC colleges (no Stanford, no Ivies)	Demographic analysis; long-term trends; independent verification
Athlete Commit Pages	School athletics page; search "signing day" + school name	Name, sport, destination college for each recruited athlete	Only available at schools that publish (very few do)	Decomposing athlete vs. non-athlete placements
Aggregators (Niche, PrepReview)	niche.com, prepreview.com, chicardgoschool.com	Cross-school comparisons; NSC-verified enrollment (Niche)	Methodology details; year-specific data; may lag 1-2 years	Quick comparisons when you can't access primary sources

Data Format	What It Means	How to Read It
5 individual years, per-college counts	Gold standard — full trend visibility	Calculate per-year rates directly
3-year rolling window with counts	Smoothed average — hides single-year spikes	Divide by 3 for rough annual rate; don't add across profiles
4-year aggregate with tiers	Floor values only — "10+" could be 10 or 30	Use the tier minimum; note the uncertainty
Presence-only list (no counts)	Binary signal — school places <i>someone</i> there	Supplement with UC data and Niche for magnitude
"Accepted to" vs. "Enrolled at"	Different metrics — accepted list is 20-30% larger	Always identify the metric before comparing schools

Chapter Evidence Note

This chapter relies primarily on **Tier A** (official school data) and **Tier E** (author synthesis) evidence.

Tier A claims: School data formats (SHP per-year vs. Menlo rolling windows vs. Nueva tiers vs. Castilleja presence-only vs. Harker combined list) — verified from published school profiles and college counseling pages. UC InfoCenter availability, data fields, and ethnicity breakdowns — from

UC's public data portal. Harker UC applicant demographics (120 of 187 Asian in 2024) — from UC InfoCenter source school data. All school-specific counts (Menlo's 30 Stanford over 3 years, Harker's 34 Stanford over 3 years, etc.) from published school documents.

Tier C claims: Niche NSC methodology, PrepReview ECPI index, Chicardgo School feeder percentages — described from these platforms' published methodology pages.

Tier E claims: The recommendation to cross-validate across sources, the five-question framework for school visits, the characterization of data format choices as "design choices that favor the school's narrative," and the overall framing that format matters as much as content — these are author synthesis. The underlying data is Tier A; the interpretation is the author's judgment about what matters for parents doing their own research.

Before acting on specific numbers, verify with current school publications and UC InfoCenter data. School profiles are updated annually; the data in this chapter reflects publications available as of spring 2026.

Chapter 3: The Athlete Hook — Quantified

Who this chapter is for: T1-T2 readers — parents who have read Chapter 1's headline vs. reality gap and want to understand exactly how athletic recruitment shapes placement data. Whether your child is an athlete or not, this chapter changes how you read every school's numbers.

Athletic recruitment is the single largest hidden variable in Bay Area private school college placement data. Chapter 1 showed you that SHP's headline Ivy+ rate of 16.8% drops to 10.5% once you remove recruited athletes. This chapter goes deeper: which sports, which colleges, what the timeline looks like, and whether the athletic recruitment path makes sense for your family.

You are at a school fundraiser gala, seated next to a parent whose son just committed to play water polo at Princeton. "He's been playing since third grade," she says. "Club team, travel tournaments, the whole thing." You nod politely. Your daughter is in sixth grade, plays soccer recreationally, and gets straight A's. You drove here thinking about your school's 17% Ivy+ rate. You are now doing math in your head, and the math is not comforting.

Here is the thing the fundraiser parent will not tell you, because she may not know it herself: her son is not an outlier in the data. He is the data. At SHP, water polo alone accounts for 22 of 50 athlete-to-Ivy+ placements over five years. Her son is one of roughly four water polo players per year who commit to an Ivy+ school from this single campus. Your daughter's soccer — recreational, no club team — is not in the same universe of admissions impact. [A]

That is not a judgment. It is a structural fact about how college recruitment works, and it should change how you interpret your school's numbers.

The SHP Athlete Pipeline: Five Years of Data

SHP publishes named athlete commitment lists every year — a level of transparency almost no other Bay Area private school offers. Over five graduating classes (2021-2025), 146 athletes committed to play college sports. Fifty of those went to Ivy+ schools. [A]

Here is the year-by-year breakdown:

Year	Class Size	Total Athletes	Athletes to Ivy+	WP to Ivy+	LAX to Ivy+	Other to Ivy+	Total Ivy+	Non-Athlete Ivy+	Non-Athlete Rate
2021	155	23	3	1	2	0	28	25	16.1%
2022	155	40	20	12	5	3	25	5	3.2%
2023	171	31	8	3	1	4	28	20	11.7%
2024	149	29	12	3	4	5	30	17	11.4%
2025	160	23	6	3	1	2	22	16	10.0%
Total	790	146	50	22	13	14	133	83	10.5%

Two sports dominate this pipeline: water polo and lacrosse. Together, they account for 35 of 50 athlete-to-Ivy+ placements — 70% of the athlete hook at SHP. [A]

The 2022 class is the extreme case worth studying. That year, 40 athletes committed to play in college — nearly twice the typical year. Twenty went to Ivy+ schools. Of those twenty, twelve were water polo players (seven to Stanford, four to Princeton, one to Brown) and five were lacrosse players (three to Duke, one to Stanford, one to Penn). The non-athlete Ivy+ enrollment that year was five students out of 155 — a 3.2% rate. [A]

If you were a non-athlete family in SHP's class of 2022, your school's headline Ivy+ rate was 16.1%. Your child's realistic rate was 3.2%. That is a fivefold gap, and it was entirely invisible on the placement page.

Which Sports Feed Which Colleges

Not all sports are created equal in the recruitment pipeline. Here is where SHP athletes actually go:

****Figure 3.1:**** SHP five-year athlete commits by sport group. Water polo and lacrosse together produced 73 of 146 total commits — exactly half — but accounted for 70% of all athlete-to-Ivy+ placements.

Water Polo: The Dominant Pipeline

Water polo is SHP's signature athletic pipeline. Over five years, 44 students committed to play water polo in college — more than any other sport. Twenty-two of them went to Ivy+ schools. [A]

The destinations are concentrated:

College	WP Commits	Years Active
Stanford	10	2022 (7), 2023 (1), 2025 (2)
Princeton	8	2021 (1), 2022 (4), 2023 (1), 2024 (1), 2025 (1)
Harvard	2	2023 (1), 2024 (1)
Brown	2	2022 (1), 2025 (1)

Stanford and Princeton alone absorbed 18 of 22 Ivy+ water polo commits. This is not random — Stanford and Princeton have two of the strongest collegiate water polo programs in the country. SHP, located twenty minutes from Stanford's campus, has direct coaching and club connections to these programs. [D]

Here is what makes water polo unusual as a recruitment sport: the talent pool is shallow. Water polo is not widely played outside California, parts of the Midwest, and a handful of East Coast programs. A strong water polo player from the Peninsula has far less competition for recruitment

slots than a strong soccer or basketball player competing against a national talent pool. Coaches consistently report that this is why water polo converts to elite college placements at a rate no mainstream sport can match. [D]

Lacrosse: The East Coast Connection

Lacrosse is SHP's second major pipeline. Twenty-nine athletes committed over five years, thirteen to Ivy+ schools. [A]

College	LAX Commits	Years Active
Duke	4	2022 (3), 2024 (1)
Princeton	2	2021 (1), 2023 (1)
MIT	2	2024 (1), 2025 (1)
Harvard	1	2024
Brown	1	2024
Stanford	1	2022
Georgetown	1	2021
Penn	1	2022

Duke is the primary lacrosse destination — four commits in five years, all to a top-5 program. But lacrosse also scatters across the Ivy League and elite schools in a way water polo does not: Harvard, Brown, MIT, Georgetown, Penn, Princeton. This reflects lacrosse's broader institutional presence on the East Coast. [A]

Lacrosse has grown rapidly on the Peninsula over the past decade. Like water polo, it occupies a strategic niche: competitive enough to drive recruitment, but still newer to California — meaning less competition for roster spots than in traditional East Coast strongholds. [D]

Everything Else: Scattered Impact

The remaining 73 athlete commits spread across 20+ sports — football (12), soccer (12), volleyball (6), baseball (6), basketball (5), swimming (3), rowing (2), and various others. Of these, only 14 went to Ivy+ schools, scattered across Brown, Harvard, Yale, Penn, MIT, Duke, Northwestern, and Cornell. [A]

No single "other" sport produced more than two Ivy+ commits over five years. Football sent two to Harvard and Brown. Rowing sent two to Yale and Penn. Swimming sent two to Brown and Harvard. These are real pathways, but they are not pipelines — they are individual cases, not repeatable patterns.

A micro-case. A family we'll call the Andersons have a son who is a strong varsity swimmer at an SHP-type school. He made CCS (Central Coast Section) finals. The Andersons have been told by a club coach that "D1 is definitely in play." Over five years at SHP, exactly three swimmers committed to play in college — two to Ivy+ schools (Brown and Harvard). Swimming can work as a recruitment hook. But the pipeline is thin enough that each case is essentially *sui generis*. The Andersons should pursue it with open eyes, not with the assumption that swimming has the same structural advantage as water polo at their school.

How Athletic Recruitment Actually Works

If you are a non-athlete family, you can skip this section. If you are considering the athletic recruitment path, this is the timeline you need to understand.

Elementary / Middle School

Ages 8-10: Start club sport
Year-round training begins

Ages 11-13: Travel tournaments
National-level exposure starts

High School

9th-10th: Recruiting events
Coaches begin watching

Junior year: Official visits
Verbal commitments (non-binding)

****Figure 3.2:**** The athletic recruitment timeline from initial sport commitment through NLI signing. The process typically spans 6-8 years, with meaningful commitment beginning in elementary school.

The timeline, compressed

Ages 8-10: Club sport begins — not school rec league, but competitive club. For water polo on the Peninsula, this means programs like Stanford Water Polo Club or 680 Aquatics. For lacrosse, Bay Area club programs. Year-round training. This is the commitment gate: if a family is not here by age 10, the recruitment path for pipeline sports becomes significantly harder. [D]

Ages 11-13: Travel tournaments begin. College coaches attend these events to identify talent early. For water polo, Junior Olympics and US Water Polo events are key showcases. This is where coaches first notice a player. [D]

9th-10th grade: College coaches reach out (NCAA rules restrict timing — verify current regulations at ncaa.org). Unofficial campus visits happen. Academic credentials start to matter: coaches want players who will clear admissions. [A/D]

Junior year: Official campus visits. Verbal commitments — non-binding agreements where a player commits to a school. In practice, verbal commitments are honored the vast majority of the time. This is when the admissions advantage locks in. [D]

Senior fall: The National Letter of Intent (NLI) is signed during NCAA-designated signing periods. At Ivy League schools, the NLI is not used — instead, the school provides a "likely letter" and the athlete signs a financial agreement. The practical effect is the same: a reserved spot. [A]

What "recruited" means for admissions

Recruited athletes do not go through the same admissions process as other applicants. At most selective colleges, the athletic department provides the admissions office with a list of recruits — often called a "coach's list" or "tip list." These applicants receive a significant admissions advantage. At Harvard, litigation in the SFFA case revealed that recruited athletes were admitted at rates exceeding 80%, compared to roughly 5% for the general applicant pool. Other Ivy League schools operate similarly. [A]

This is not a minor edge. It is a parallel admissions channel with fundamentally different acceptance rates. When you see that SHP sent 10 water polo players to Stanford over five years, those players were not competing against the 3.7% general admission rate. They were on the coach's list, reviewed in a process where the vast majority of listed athletes are admitted. [A/E]

Why Other Schools Don't Publish This Data

SHP is unusual. Most Bay Area private schools do not publish athlete commitment lists. There is no conspiracy here — schools simply have no incentive to decompose their headline numbers. A school that reports "22% of graduates attend Ivy+ schools" looks better than one that reports "14% of non-athlete graduates attend Ivy+ schools," even though the second number is more useful to most families. [E]

How to estimate the athlete share at any school

1. **Check the school's athletics page.** Schools with strong pipelines feature signing ceremonies and "college commitment" photos. Count them. [E]
 2. **Look for sport-specific strength signals.** Does the school win CCS or NCS championships in specific sports? Championship programs produce D1 recruits. [D]
 3. **Cross-reference recruiting databases.** NCSA and similar sites sometimes list commits by high school. Incomplete but directional. [E]
 4. **Ask directly.** "Of your Ivy+ placements last year, how many were recruited athletes?" Most admissions offices have never been asked. [E]
 5. **Apply a rough heuristic.** At Bay Area private schools with strong athletics, estimate 25-40% of Ivy+ placements involve recruited athletes. At schools with dominant water polo, lacrosse, or rowing, the share may be higher. At academically-focused schools (Nueva, Crystal Springs), near zero. [E]
-

The "Soft Athlete" Path

Not every athlete is recruited. Many students play varsity sports, earn All-League honors, even compete at CCS — and are never on a college coach's radar. What is varsity participation worth in admissions without the recruitment hook?

A micro-case. A family we'll call the Raos have a daughter who is a varsity tennis player. She is the number two singles player on her school's team. She made the second round of CCS. She also has a 4.2 GPA and strong test scores. The Raos have been told by a private counselor that her tennis "will look great on the application." They want to know: how much does it actually help?

The honest answer: it helps, but not in the way recruitment helps. Varsity athletics demonstrates commitment, time management, and physical discipline. Admissions officers consistently report valuing these qualities. But a non-recruited varsity athlete is in the general applicant pool, competing at the 4-7% admit rate, not on the coach's list at 80%+. [D/E]

The difference is not one of degree. It is one of kind. A recruited athlete has a reserved seat. A varsity athlete has a small plus factor on an application that will be evaluated holistically. The tennis player's sport may be the difference between "admit" and "waitlist" in a close call — but it will not transform a borderline application into a lock. [E]

Many families invest heavily in a sport through high school believing varsity status provides significant admissions leverage. For recruitment-level athletes, it does. For the rest, the impact is real but modest — comparable to strong commitment in any other extracurricular domain. [D/E]

What This Chapter Is Not Saying

This chapter is not saying athletic recruitment is unfair. Recruited athletes have trained for years, often since elementary school, at significant family cost in time and money. They earned their spots.

This chapter is not saying your child should play water polo. Starting a sport for the purpose of college recruitment, particularly after age 10, is generally too late for the pipeline sports that produce Ivy+ commits. Coaches consistently say they can identify players who started for strategic reasons — the commitment gap shows up in performance and dedication. [D]

This chapter is not saying non-athlete families are disadvantaged. SHP's non-athlete Ivy+ rate of 10.5% is strong. It means roughly one in ten non-recruited graduates enrolls at a top university. That rate competes favorably with the most competitive public high schools in the Bay Area.

What this chapter is saying: **the athlete hook is a structural feature of college placement data, not an anomaly. Understanding it lets you read every school's numbers accurately — and make decisions based on what is real for your family, not what the composite average suggests.**

Should Your Family Pursue Athletic Recruitment?

This is a decision framework, not a recommendation. Honest answers to these questions will tell you whether the recruitment path is realistic.

Is your child already on the path? If your child is 12 or older and not already training year-round in a club program for a recruitment-viable sport, the window for pipeline sports (water polo, lacrosse, rowing) is closing or closed. Other sports have different timelines — golf and tennis recruitment can start later — but the high-volume Ivy+ pipelines favor early starters. [D]

Is it the right sport? Water polo and lacrosse produce outsized Ivy+ results at Peninsula schools because the collegiate talent pool is small and the local club infrastructure is strong. Soccer, basketball, and baseball have much larger national talent pools — a strong Bay Area player may not be nationally competitive. Swimming and track are individually meritocratic (times don't lie), which makes the path clearer but no easier. [D/E]

Can your family sustain the commitment? Club sports on the Peninsula cost \$5,000-\$15,000 per year in fees alone, plus travel, equipment, and time. The commitment is year-round. For water polo, this means pool time five to six days per week, plus weekend tournaments. For lacrosse, fall ball, indoor winter league, and spring season create a nearly continuous calendar. Families who start this path should understand it as a 6-8 year commitment, not a 2-year experiment. [D]

Is your child intrinsically motivated? Coaches and admissions officers both report that the most successful recruited athletes are those who play because they love the sport, not because their parents identified a strategic pathway. This is not soft advice — it is practical. The commitment required to reach recruitment level is intense enough that externally motivated athletes typically drop out or plateau before the payoff arrives. [D]

****Figure 3.3:**** Decision framework for evaluating the athletic recruitment path. Most families arrive at one of the yellow boxes — which is not a failure. It is useful information that redirects energy toward strategies with higher expected value.

Quick Reference

Question	Answer	Source
What share of SHP's Ivy+ placements are athletes?	50 of 133 (37.6%) over 5 years	SHP athlete + placement data [A]
Which sports dominate the Ivy+ pipeline?	Water polo (22) and lacrosse (13) = 70% of athlete-to-Ivy+	SHP athlete commits [A]
Where do water polo recruits go?	Stanford (10), Princeton (8), Harvard (2), Brown (2)	SHP athlete commits [A]
Where do lacrosse recruits go?	Duke (4), Princeton (2), MIT (2), Harvard (1), Brown (1)	SHP athlete commits [A]
What is the non-athlete Ivy+ rate at SHP?	10.5% (83 of 790 over 5 years)	Calculated from SHP data [A/E]
Worst single year for non-athletes?	2022: 3.2% (5 of 155) — 20 of 25 Ivy+ were athletes	SHP data [A]
When does the recruitment pipeline start?	Club sport by ages 8-10; serious travel by 11-13	Coach and parent reports [D]
What is varsity participation worth without recruitment?	Small positive factor in holistic review — not a reserved seat	Admissions officer consensus [D]
How to estimate athlete share at other schools?	Check signing ceremonies, CCS titles, ask directly. Estimate 25-40% at sports-strong schools.	Author synthesis [E]

Chapter Evidence Note

This chapter relies primarily on **Tier A** (official school data) and **Tier D** (community patterns) evidence, with **Tier E** (author synthesis) for interpretive framing.

Tier A claims: SHP athlete commitment lists (names, sports, colleges) for classes 2021-2025; SHP college placement data (enrolled counts by year); class sizes from school profile PDFs; NCAA NLI signing period dates; Harvard SFFA litigation data on recruited athlete admit rates — all from official publications and court records.

Tier D claims: Recruitment timeline norms (when club sports start, when coaches begin watching); water polo talent pool dynamics (shallow national pool favoring California players); lacrosse growth trajectory on the Peninsula; club sport cost ranges (\$5,000-\$15,000/year); coach and admissions officer reports on intrinsic motivation and "soft athlete" admissions impact — these are consistent community patterns, not controlled studies.

Tier E claims: The 25-40% athlete share heuristic for non-publishing schools; the characterization of varsity participation as "small plus factor"; the decision framework for evaluating the recruitment path; the recommendation to ask schools directly about athlete share — these are author synthesis based on the data and community patterns above.

All SHP data in this chapter is from official school publications covering graduating classes 2021-2025. Recruitment timelines and cost estimates reflect 2024-2025 Bay Area norms. NCAA contact rules change periodically — verify current regulations at ncaa.org before acting on specific timeline claims.

Chapter 4: School by School — The Real Numbers

Who this chapter is for: T2 readers — parents already at or seriously considering one of these schools, who want standardized, honest data for comparison. You should read Chapters 1-3 first.

Every school in this chapter publishes college placement data. None of them publish it the same way. One gives you five years of applied-accepted-enrolled counts by college. Another gives you a three-year aggregate with no per-year breakdown. A third gives you four-year tiers — "10 or more," "5 or more," "1 or more" — that tell you a school sent at least ten students to Harvard over four years without telling you if that means ten or forty. This chapter standardizes what they publish so you can compare them. Where the data won't support comparison, we say that clearly. [E]

You are standing at a school fair in downtown Palo Alto, and four schools have booths within fifty feet of each other. Each one has a poster with college logos. Each one looks impressive. You cannot tell, from the posters, which school sends the most students to Ivy+ colleges, because each poster uses different counting rules, different timeframes, and different definitions of what counts. By the end of this chapter, you will know what each school's data actually says — and what it carefully does not say.

How to Read This Chapter

Each school profile follows the same structure:

1. **What they publish** — the format, timeframe, and metric (enrolled vs. accepted vs. "attended")
2. **Ivy+ numbers** — standardized to the best available data window
3. **Top destinations** — where graduates actually go (not just the prestige names)
4. **UC admissions** — from UC InfoCenter, which is standardized across schools [A]
5. **Data quality notes** — what you should and shouldn't conclude from this school's data

Ivy+ means the eight Ivies plus Stanford, MIT, Caltech, Duke, UChicago, Northwestern, and Johns Hopkins — fifteen schools total. This definition is the same across every profile. [E]

The Private Schools

Sacred Heart Preparatory (SHP) — Atherton

What they publish: Five years of per-college data (2021-2025) with applied, accepted, and enrolled counts. Also publishes annual athlete commitment lists. This is the gold standard of data transparency among Bay Area private schools. [A]

Metric	Value
Class size	149-171 (5-yr range); avg 158
Data window	5 years (2021-2025), per-year
Ivy+ enrolled (5-yr total)	124
Ivy+ rate (headline)	15.7% avg
Athletes to Ivy+ (5-yr)	~50
Non-athlete Ivy+ rate	~10.5%

Top destinations (5-yr enrolled): Santa Clara (35), Stanford (28), UC Berkeley (22), Cal Poly SLO (22), UCLA (20), USC (19), Notre Dame (18), TCU (17), SMU (17). [A]

UC admissions (2024): 86 applied, 53 admitted (62% admit rate). Asian applicants: 23 applied, 16 admitted (70%). White applicants: 36 applied, 19 admitted (53%). [A]

Data quality: Excellent. SHP is the only school where you can decompose athlete vs. non-athlete placements and track year-over-year volatility. The non-athlete Ivy+ rate ranged from 3.2% (2022) to 16.1% (2021) — a massive swing driven by athletic cohort composition. If you use SHP as your benchmark, use the five-year non-athlete average (10.5%), not any single year. [E]

The Harker School — San Jose

What they publish: Three-year combined enrollment list (Classes of 2023-2025) with counts per college. No per-year breakdown. No applied or accepted data. No athlete data. [A]

Metric	Value
Class size	~260 (estimated from UC applicant data)
Data window	3 years combined (2023-2025)
Ivy+ enrolled (3-yr total)	139
Ivy+ rate (estimated)	~17.8% per year
Athlete data	Not published

Top destinations (3-yr enrolled): Stanford (34), Carnegie Mellon (27), UC Berkeley (26), NYU (26), Purdue (25), UCLA (17), UChicago (16), Santa Clara (16), Columbia (15), UT Austin (15). [A]

UC admissions (2024): 187 applied, 132 admitted (71% admit rate). Asian applicants: 120 applied, 81 admitted (68%). White applicants: 23 applied, 18 admitted (78%). [A]

Data quality: Moderate. The three-year combined window hides year-to-year volatility entirely. You cannot tell if Stanford took 15 students one year and 5 the next, or a steady 11 per year. Without athlete data, the Ivy+ rate cannot be decomposed. Harker's UC applicant pool is 64% Asian — the highest of any school in this chapter — which means internal competition dynamics from Chapter 5 are strongest here. The estimated class size (~260) makes Harker's 17.8% headline Ivy+ rate look comparable to SHP's 15.7%, but without athlete decomposition, the true non-athlete rate is unknown. [E]

A micro-case. A family we'll call the Sharmas are comparing Harker and SHP. On paper, Harker's Ivy+ rate (17.8%) beats SHP's (15.7%). But Harker has nearly twice SHP's class size, meaning the raw number of Ivy+ admits is higher while the rate is only modestly different. The Sharmas — engineers, both — want to know the non-athlete rate at Harker. Nobody can tell them. The data does not exist in public form. What the Sharmas can see: Harker sends 34 students to Stanford in three years (11.3/year) from a class of ~260. SHP sends 28 in five years (5.6/year) from a class of ~158. Per-student, the Stanford rates are 4.3% (Harker) vs. 3.5% (SHP). Close enough that the school choice should be driven by other factors. [E]

Menlo School — Atherton

What they publish: Three-year rolling aggregates. The current profile shows Classes of 2023-2025 enrolled. Prior profiles showed 2021-2023 and 2020-2022, creating overlapping windows. No per-year breakdown. No athlete data. [A]

Metric	Value
Class size	143-146
Data window	3-yr rolling (most recent: 2023-2025)
Ivy+ enrolled (3-yr, 2023-2025)	112
Ivy+ rate (estimated)	~26.1% per year
National Merit Semifinalists	5-12 per year
Athlete data	Not published

Top destinations (3-yr, 2023-2025 enrolled): Stanford (30), UChicago (17), Northwestern (10), Cornell (9), Dartmouth (8), Harvard (7), Duke (7). [A]

UC admissions (2024): 115 applied, 68 admitted (59% admit rate). Asian applicants: 36 applied, 25 admitted (69%). White applicants: 36 applied, 20 admitted (56%). [A]

Data quality: Needs careful interpretation. Menlo's 26.1% headline Ivy+ rate is the highest of any school in this chapter. But the overlapping three-year windows mean you cannot isolate individual years or track trends. The rate may also reflect athletic recruitment — Menlo has strong lacrosse and water polo programs — but no public athlete data exists to verify. Stanford is Menlo's dominant destination: 30 students over three years, or 10 per year from a class of ~143. That is a 7% Stanford enrollment rate, the highest of any school profiled. [E]

The overlapping window issue is worth understanding. Menlo's 2021-2023 window shows 23 Stanford enrollees. The 2023-2025 window shows 30. These windows share the Class of 2023, so you cannot simply add them. A parent who sees "23 Stanford" on one profile and "30 Stanford" on the next might think placements surged. They may have — or the overlap may make the change look larger than it is. [E]

****Figure 4.1:**** Data transparency varies dramatically across Bay Area private schools. SHP publishes the most granular data; several schools publish only name lists without counts.

Castilleja School — Palo Alto

What they publish: A list of colleges where recent graduates "matriculated," with bold formatting to indicate enrollment. One year's data (Class of 2025). No counts per college. [A]

Metric	Value
Class size	51
Data window	1 year (2025)
Ivy+ enrolled (confirmed minimum)	11 (at least 1 each to 11 Ivy+ schools)
Ivy+ rate (minimum estimate)	~21.6% (could be higher)
Mean GPA (weighted)	4.14
College-going rate (4-yr)	97%

Top destinations: Cannot determine — no counts published. The list includes Harvard, Princeton, Yale, Stanford, Brown, Cornell, Dartmouth, Duke, Northwestern, UPenn, UChicago. [A]

UC admissions (2024): 47 applied, 25 admitted (53% admit rate). Asian applicants: 23 applied, 10 admitted (43%). White applicants: 9 applied, 5 admitted (56%). [A]

Data quality: Limited. With a class of 51, Castilleja is the second-smallest school profiled. At least 11 Ivy+ schools appear on the 2025 list, but without counts, the minimum (11 students to 11 schools) and maximum (potentially more per school) are unknown. Small class sizes amplify volatility — two or three exceptional students in a class of 51 can move the Ivy+ rate by 4-6 percentage points. The UC admit rate (53%) is the lowest of any private school profiled, driven partly by a notably low Asian admit rate (43%). [E]

The Nueva School — San Mateo

What they publish: Four-year aggregate placement data in tiers: "10 or more," "5 or more," "1 or more." Two overlapping windows: Classes 2020-2023 and Classes 2021-2024. [A]

Metric	Value
Class size	108-112
Data window	4-yr tiers (most recent: 2021-2024)
Ivy+ enrolled (4-yr, minimum estimate)	~121
Ivy+ rate (estimated from tier minimums)	Not reliably calculable
Mean SAT	1510
Mean ACT	33-34
National Merit Semifinalists	19-25 per year

What the tiers actually tell you (2021-2024 window): [A]

Tier	Colleges in Ivy+ list
10 or more (4-yr)	Harvard, Stanford, Princeton, Columbia, Cornell, Brown, UPenn, Northwestern, UChicago
5 or more (4-yr)	MIT, Yale, Caltech, Duke, Dartmouth
1 or more (4-yr)	JHU

UC admissions (2024): 98 applied, 63 admitted (64% admit rate). Asian applicants: 40 applied, 30 admitted (75%). White applicants: 31 applied, 19 admitted (61%). [A]

Data quality: Frustrating. Nueva has some of the strongest test scores and National Merit numbers of any school profiled. But the tier system makes precise comparison impossible. "10 or more to Harvard over four years" could mean 10 or 40. The tier minimums sum to 121 Ivy+ placements over four years from classes averaging 110, which would imply a 27.5% annual rate — but the actual number could be significantly higher. Nueva's refusal to publish exact counts, despite clearly having strong placement, is itself informative: it likely reflects a philosophical choice about not defining the school by college placement. [E]

Crystal Springs Uplands School — Hillsborough

What they publish: A four-year aggregate list (Classes 2022-2025) of colleges where graduates enrolled. No counts — just confirmed minimums of 1 per college. [A]

Metric	Value
Class size	90
Data window	4-yr (2022-2025), name list only
Ivy+ enrolled (confirmed minimum)	14 (at least 1 each to 14 of 15 Ivy+ schools)
Ivy+ rate (minimum estimate)	~3.9% per year (could be much higher)

UC admissions (2024): 66 applied, 42 admitted (64% admit rate). Asian applicants: 39 applied, 27 admitted (69%). White applicants: 11 applied, 4 admitted (36%). [A]

Data quality: Very limited. The name list confirms Crystal Springs placed at least one graduate at 14 of 15 Ivy+ schools over four years. That is breadth. But without counts, you cannot determine depth. The school might have sent 5 students to Stanford over four years or 20. The UC data is more revealing: 66 applications from a class of 90 means 73% of Crystal Springs students apply to UCs. The Asian share of UC applicants has grown from 44% (2020) to 59% (2024), a significant demographic shift worth watching. [E]

Pinewood School — Los Altos Hills

What they publish: Four-year aggregate (Classes 2022-2025) with two tiers: 2+ graduates confirmed (marked with asterisk) and minimum 1 confirmed. [A]

Metric	Value
Class size	44-54 (varies significantly)
Data window	4-yr (2022-2025)
Ivy+ enrolled (confirmed minimum)	17
AP courses	17
National Merit Semifinalists	2-4 per year
College-going rate (4-yr)	100%

UC admissions (2024): 26 applied, 19 admitted (73% admit rate). Asian applicants: 18 applied, 14 admitted (78%). [A]

Data quality: Limited by class size. Pinewood's graduating classes range from 44 to 54 students — the smallest in this chapter. The 17 confirmed Ivy+ placements over four years (~4.25/year) from a class averaging ~49 suggests a rate around 8.7%, but the margins of error on a class this small are enormous. One student more or less changes the rate by 2 percentage points. The UC data is the most reliable indicator: a 73% UC admit rate is strong, and the 78% Asian admit rate is the highest of any school profiled. [E]

Woodside Priory School — Portola Valley

What they publish: No standardized placement data was found in public sources. [A]

Metric	Value
Class size	~45-55 (estimated from UC applicant data)
Data window	None publicly standardized
Ivy+ data	Not available in public record

UC admissions (2024): 40 applied, 27 admitted (68% admit rate). Asian applicants: 9 applied, 4 admitted (44%). White applicants: 10 applied, 4 admitted (40%). [A]

Data quality: Minimal. Woodside Priory is the only school in this chapter with no publicly available Ivy+ placement data in any standardized form. The UC data suggests a small school with modest UC applicant volume. Without placement data, no Ivy+ analysis is possible. [E]

The Comparison Table

This is the table every parent wants. It is also the table most likely to mislead, because the data behind each row comes from different timeframes, formats, and counting methods. Read the footnotes before drawing conclusions.

****Figure 4.2:**** Ivy+ rate comparability across Bay Area private schools. Only three schools publish enough data for even approximate rate calculations; two more provide tier-based estimates; two offer only name lists.

School	Class Size	Ivy+ Rate	Data Window	Data Quality	Top Destination
SHP	158 avg	10.5% (non-ath) / 15.7% (all)	5-yr per-year	Excellent	Stanford (28)
Harker	~260	~17.8% (no decomp)	3-yr combined	Moderate	Stanford (34)
Menlo	~143	~26.1% (no decomp)	3-yr rolling	Moderate	Stanford (30)
Nueva	~110	27.5%+ (tier min)	4-yr tiers	Low (tiers)	Stanford (10+)
Castilleja	51	21.6%+ (min)	1-yr list	Low (no counts)	Multiple (1+ each)
Crystal Springs	90	3.9%+ (min)	4-yr list	Very low	Unknown
Pinewood	~49	~8.7%	4-yr partial	Low	Stanford (2+)
Priory	~50	N/A	None	None	Unknown

Critical caveat: Only SHP's rate is decomposed into athlete and non-athlete. Every other school's headline rate includes recruited athletes. If Menlo or Harker have athletic recruitment pipelines comparable to SHP's, their non-athlete rates could be 4-6 percentage points lower than the headlines suggest. [E]

The Public Schools

Three public high schools are included for comparison. Their data comes from different sources: user-collected spreadsheets (cross-validated where possible) and UC InfoCenter. [A/D]

Gunn High School — Palo Alto

Metric	Value
Class size	447
Ivy+ enrolled (approx annual)	149
Ivy+ rate	~33.3%
Top Ivy+ destinations	Stanford (48), Cornell (13), MIT (11), UChicago (11), UPenn (11), Brown (10)
UC Berkeley enrolled (annual)	~75

Palo Alto High School (Paly) — Palo Alto

Metric	Value
Class size	476
Ivy+ enrolled (approx annual)	100
Ivy+ rate	~21.0%
Top Ivy+ destinations	Stanford (23), UChicago (13), Brown (10), Northwestern (10), Cornell (7)
UC Berkeley enrolled (annual)	~49

Lynbrook High School — San Jose

Metric	Value
Class size	472
Ivy+ enrolled (approx annual)	74
Ivy+ rate	~15.7%
Top Ivy+ destinations	Cornell (12), Stanford (11), UPenn (11), MIT (10), JHU (7)
UC Berkeley enrolled (annual)	~56

Data quality note for all three public schools: These numbers come from user-collected data (described as approximately 2021-2023 three-year averages, rounded). They have not been verified against official school publications. Treat them as directional estimates, not precise figures. The public school numbers appear to use a similar Ivy+ definition but may include different counting conventions. [D]

The ROI Question

A micro-case. A family we'll call the Garcias have a daughter in fourth grade. She is a strong student at a public elementary school in Palo Alto. The Garcias are weighing whether to apply to Menlo or Harker for sixth grade entry, or stay in the Palo Alto district and attend Gunn. The tuition question is \$50,000 per year for seven years (grades 6-12), or approximately \$350,000 total. [E]

Here is what the placement data suggests:

Path	Ivy+ Rate (headline)	Annual Cost	7-Year Cost	Ivy+ Rate per \$100K
Gunn (public)	~33.3%	\$0	\$0	N/A — free
Menlo (private)	~26.1%	~\$55,000	~\$385,000	~6.8%
Harker (private)	~17.8%	~\$55,000	~\$385,000	~4.6%
SHP (private, non-athlete)	~10.5%	~\$55,000	~\$385,000	~2.7%

On a pure placement-rate basis, Gunn — a free public school — has a higher headline Ivy+ rate than any private school profiled. [A/D/E]

This table is deliberately provocative, and it is also deliberately incomplete. Chapter 6 explains why the ROI calculation is more nuanced than "higher rate, lower cost = better." The answer depends on what the private school premium actually buys — and for whom. [E]

What This Chapter Is Not Saying

This chapter is not saying some schools are better than others. A school's Ivy+ rate does not capture the quality of its teaching, the health of its community, or the happiness of its students.

This chapter is not saying low-data schools are hiding bad results. Small schools (Castilleja, Pinewood, Priory) may choose not to publish counts precisely because their small class sizes make individual students identifiable. That is a privacy decision, not an evasion.

This chapter is not saying the public school numbers are directly comparable to the private school numbers. The data sources, collection methods, and student populations are different enough that the comparison table should be read as directional, not as a controlled experiment.

What this chapter is saying: **the data landscape is uneven, and the unevenness itself is data.** Schools that publish more tell you more. Schools that publish less leave you guessing. When you are spending \$50,000 per year, you should know how much guessing you are doing. [E]

****Figure 4.3:**** Decision tree for comparing any two schools' placement data. Most comparisons fail at the first or second gate because schools do not publish data in compatible formats.

Quick Reference

What you want to know	Where to look	What to watch for
Ivy+ rate for SHP	This chapter — 10.5% non-athlete (5-yr)	Best-documented school; use non-athlete rate
Ivy+ rate for Harker	This chapter — ~17.8% headline (3-yr)	No athlete decomposition; includes athletic recruits
Ivy+ rate for Menlo	This chapter — ~26.1% headline (3-yr)	Overlapping windows; no athlete data; highest headline rate
Ivy+ rate for Nueva	This chapter — 27.5%+ (tier minimums)	Tiers give floors, not actuals; could be much higher
Ivy+ rate for Castilleja	This chapter — 21.6%+ (1-yr minimum)	Tiny class (51); one year only; high volatility
Ivy+ rate for small schools	This chapter — limited	Crystal Springs, Pinewood, Priory: minimal count data
Public school comparison	This chapter — Gunn 33.3%, Paly 21.0%, Lynbrook 15.7%	User-collected data; different methodology; directional only
UC admissions by ethnicity	UC InfoCenter (free, searchable)	Standardized and reliable; best cross-school comparison tool
Athlete impact on rates	Ch. 3 for SHP details; unknown at other schools	If no athlete data, assume headline rate is inflated

Chapter Evidence Note

This chapter relies primarily on **Tier A** (official school data and UC InfoCenter) and **Tier E** (author synthesis) evidence, with some **Tier D** (user-collected public school data).

Tier A claims: Class sizes, Ivy+ enrolled counts (where published), UC admissions data by school and ethnicity, GPA and test score data from school profiles — all from official school publications or UC InfoCenter. Source URLs are in the database.

Tier D claims: Public school Ivy+ enrollment numbers (Gunn, Paly, Lynbrook) are from user-collected spreadsheets described as three-year averages, approximately 2021-2023, rounded. These have not been verified against official school publications and should be treated as directional estimates.

Tier E claims: Rate calculations, cross-school comparisons, the ROI table, data quality assessments, and the interpretation that data transparency varies systematically across schools — all author synthesis. The comparison table carries particular E-tier risk because it compares numbers from incompatible data sources.

Before making decisions based on specific numbers, verify with current school publications. Ivy+ definitions may vary. Public school data should be cross-validated with school-published college placement pages where available.

Chapter 5: The Asian Parent Reality

Who this chapter is for: T2 readers — committed parents who have already decided on private school and need to understand how demographic composition shapes college admissions outcomes. Many readers of this chapter will be Asian American. This chapter is written for them, not about them.

The demographic composition of your child's school determines the internal competition pool. Post-SFFA, the race-based ceiling has been removed but replaced with socioeconomic proxies that disadvantage affluent Bay Area private school families of all races — and Asian families disproportionately. Understanding this structure is the first step toward making it work for you.

You are at the Harker School open house in San Jose, a Sunday morning in October. Your daughter is in third grade. The facilities are spectacular — a new STEM wing, gleaming labs, a campus that looks like a small college. The admissions director is giving the pitch: top college placements, rigorous academics, world-class faculty. You are impressed. Then you walk into the student center, and you notice something. About two-thirds of the families around you look like yours. Chinese, Indian, Korean, Vietnamese. You scan the room. It is not a vague impression. It is a demographic fact.

Later that night, you pull up the UC InfoCenter — the University of California's public admissions database, which reports applicants by high school and ethnicity. You type in Harker. The number comes back: 120 Asian students applied to UC schools from Harker in 2024, out of 187 total. That is 64%. You type in Sacred Heart Preparatory. Twenty-three Asian applicants out of 86. That is 27%.

Two schools. Both on the Peninsula. Both charging north of \$50,000 a year. But the competition landscape inside each school is radically different — and that difference will follow your daughter through every college application she files.

The Demographic Map

The UC InfoCenter is the only public data source that reports college applicants by high school and ethnicity. It is official UC data — not estimates, not surveys, not school self-reports. Every number below comes from this source. [A]

Here is what the Asian share of UC applicants looks like across all eight private schools in our dataset, averaged over five years (2020-2024):

School	Avg Asian UC Applicants	Avg Total UC Applicants	Asian Share
Harker	120	182	66%
Pinewood	14	28	51%
Crystal Springs	31	59	52%
Nueva	34	79	43%
Castilleja	16	41	40%
Menlo	31	95	33%
Woodside Priory	11	44	25%
Sacred Heart Prep	21	86	24%

The range is enormous. Harker's student body is nearly two-thirds Asian. Sacred Heart's is less than one-quarter. Priory is similar to Sacred Heart. Menlo sits in the middle third. Crystal Springs and Pinewood are majority-Asian. [A]

These numbers measure UC applicants, not enrolled students, but for Bay Area private schools with near-100% college application rates, UC applicant data is a reliable proxy for overall class composition. [E]

Figure 5.1: Asian share of UC applicants across eight Bay Area private schools (2020-2024 average), grouped into three tiers. UC InfoCenter data.

What "Internal Competition" Actually Means

A number — 66% or 24% — does not mean much on its own. What matters is what it implies for your child's college application.

College admissions offices read applications in context. They know which high school you come from. They know its demographic profile. When an admissions reader at Stanford picks up an application from Harker, they are reading it alongside every other Harker application — and mentally noting that two-thirds of Harker's graduating class is Asian. When they pick up an application from Sacred Heart, the context is different: roughly one-quarter Asian. [E]

Here is the concrete math for 2024. Harker sent 120 Asian students applying to UC schools. Sacred Heart sent 23. Both schools produce strong students. But a college admissions office evaluating Harker applicants is looking at five times as many Asian applicants with similar profiles — similar GPAs, similar test scores, similar extracurricular patterns — from a single school. [A]

This is not about quotas. It is about differentiation. Admissions officers at selective schools are building a class. They want diversity of perspective, background, and profile within each incoming cohort. When 120 applicants from one school share a similar demographic and academic profile, standing out requires more than being excellent. It requires being distinctly excellent in a way that the other 119 are not. [E]

Consider a micro-case. A family we'll call the Raos have twin sons at Harker — strong students, both in robotics and math team, both play piano. At their school, they are surrounded by peers with nearly identical profiles: Asian, STEM-strong, musically trained, high-achieving. When their applications reach Stanford or MIT, they arrive alongside dozens of similar applications from the same school. The Raos' twins are excellent. They are also, from an admissions reader's perspective, not unusual.

Now consider the same twins at Menlo, where Asian students make up 33% of UC applicants. They are still excellent. But in Menlo's context, they are part of a smaller cohort with their profile. They stand out more — not because they are better, but because the background contrast is different. The admissions reader has fewer "compare-to" applications from the same school.

This is not a theory. It is the structural logic that admissions consultants describe when they talk about "school context" — the documented practice where admissions offices evaluate applicants relative to their high school peers, not just against the national pool. [C]

The Post-SFFA Landscape

In June 2023, the Supreme Court ruled in *SFFA v. Harvard* that race-conscious admissions at selective universities was unconstitutional. For Asian American families, this was supposed to be the decision that removed the ceiling. The reality is more complicated. [A]

Who Gained, Who Didn't

Two admissions cycles have now completed under race-neutral policies. The data from the Classes of 2028 and 2029 tells a split story:

School	Pre-SFFA Asian %	Class of 2028	Class of 2029	Net Change
Harvard	30%	37%	41%	+11 pp
MIT	40%	47%	38%	-2 to +7 pp
Columbia	30%	39%	—	+9 pp
Stanford	~41%	41%	44%	+3 pp
Yale	25%	24%	30%	+5 pp
Princeton	26%	24%	27%	+1 pp
Duke	35%	29%	25%	-10 pp

Sources: Harvard Crimson, MIT's The Tech, Columbia Spectator, Stanford Daily, Yale Daily News, Daily Princetonian, Duke Chronicle — all L2. [C]

****Figure 5.2:**** Post-SFFA Asian enrollment changes at seven elite universities, grouped by outcome. Two-year data (Classes of 2028 and 2029). Data from campus newspapers.

The pattern is not random. STEM-heavy institutions (MIT, Caltech) saw the largest initial gains — consistent with the fact that their applicant pools were already disproportionately Asian, and removing race as a factor let the underlying pool composition flow through. Holistic admissions schools (Harvard, Yale, Princeton) showed smaller or mixed results. Duke is an outlier: Asian enrollment dropped significantly in both post-SFFA cycles, which triggered a legal threat from SFFA itself. [C]

Two important caveats. First, MIT's swing from 47% to 38% in a single year shows how much normal statistical noise exists — a 9-point swing that likely reflects applicant pool variation, not policy change. Researchers had predicted the average national gain for Asian Americans from SFFA would be less than 2 percentage points. The school-level data is noisier than the national average. Second, multiple universities changed their racial classification methodology (adopting IPEDS standards) at the same time they implemented race-neutral admissions, making direct year-over-year comparisons less reliable than they appear. [C]

The Stanford Legacy Ban

One structural change matters more for Bay Area families than any SFFA data point: California's AB 1780, signed by Governor Newsom in September 2024, bans legacy and donor preferences at all California private nonprofit universities — including Stanford — effective for students entering fall 2026. [A]

This is not a symbolic gesture. Research from the Harvard SFFA trial showed legacy applicants were admitted at 5.7 times the rate of comparable non-legacies. At Harvard, Yale, and Princeton, approximately 43% of white admits had ALDC status (athlete, legacy, dean's list, children of faculty) versus roughly 15% of Asian admits. Legacy preferences were, structurally, one of the largest remaining advantages for white applicants over Asian applicants at these schools. [C]

Stanford is the most important college destination for Bay Area private school families. Removing legacy there is a concrete, measurable, structural positive for Asian applicants who rarely benefit from legacy connections at a school founded in 1891. Harvard, Yale, Princeton, and Duke retain legacy preferences — at those schools, the old dynamics persist. [E]

The Socioeconomic Proxy Problem

Here is the part that gets less attention. After SFFA banned race-conscious admissions, selective universities pivoted to socioeconomic proxies for diversity. These include first-generation college status, Pell Grant eligibility, neighborhood housing data, single-parent household status, and geographic underrepresentation. Some institutions use algorithmic models that combine factors statistically correlated with race — like neighborhood housing turnover and criminal-justice involvement rates — to identify applicants from underrepresented communities without directly asking about race. [C]

These proxies are legal. They are also structurally irrelevant to your family.

If you are an Asian parent paying \$55,000 a year in tuition at Harker or Menlo or Crystal Springs, your child is, by definition, not first-generation, not Pell-eligible, and not from an underrepresented ZIP code. The socioeconomic diversity machinery provides exactly zero boost. This is true regardless of race — a white family at these schools gets no socioeconomic boost either. But it falls disproportionately on Asian families because Asian families are overrepresented at expensive Bay Area private schools. At Harker, where 66% of UC applicants are Asian, the socioeconomic proxy effectively filters against two-thirds of the student body. [E]

Consider a second micro-case. A family we'll call the Wangs came to the U.S. from Shanghai fifteen years ago. Both parents have PhDs from Berkeley. Their daughter attends Crystal Springs Uplands. They are first-generation immigrants — they were the first in their families to come to America. But they are not "first-generation college students" by the admissions definition, which means first in the family to attend college at all. Their income puts them well above Pell eligibility. Their ZIP code in Hillsborough is one of the wealthiest in the country. Every socioeconomic proxy reads them as privileged. The fact that the father grew up in a rural village in Anhui province and was the first in his village to attend university — that context does not register in the proxy system.

The Wangs are not unusual. This profile — immigrant family, educated parents, high income, first-generation in the American sense but not in the admissions-office sense — is extremely common at Bay Area private schools. The post-SFFA socioeconomic framework was designed to maintain diversity after race was removed as a direct factor. For families like the Wangs, it creates a structural gap: neither the old race-based system nor the new socioeconomic system works in their favor. [E]

What Asian Parents Can Actually Control

The structural dynamics above are real, and you cannot change them. What you can change is how you position within them.

School choice is a demographic strategy. This is not the only reason to choose a school — pedagogy, culture, commute, and community matter. But pretending demographics don't affect admissions outcomes is willful blindness. At Harker, your Asian child is one of 120 Asian UC applicants. At Sacred Heart, they are one of 23. The academic programs at both schools are strong. The internal competition landscape is structurally different. If you are in the early stages of school selection (K-5), this is one of the most consequential variables you can influence. [E]

Build a profile that breaks the pattern. Admissions officers at selective schools have described the "typical Harker applicant" in industry discussions: Asian, STEM-strong, math competition medals, piano or violin, robotics team. There is nothing wrong with this profile. It is a profile shared by dozens of applicants from the same school. Differentiation means depth in an unexpected direction — a competitive debater, a published short-story writer, a student who started a community organization in a non-STEM domain. The goal is not to hide who your child is. It is to show a dimension that the admissions reader does not see in the next thirty applications from the same school. [E]

The STEM-strong Asian female intersection. In STEM fields at elite universities, women remain underrepresented. An Asian female applicant with genuine strength in math, physics, or computer science occupies a specific intersection: overrepresented by race, underrepresented by gender within the discipline. Admissions consultants who work with Bay Area families consistently report that this intersection is one of the few where the demographic dynamics work favorably for Asian applicants — particularly at engineering-focused programs at MIT, Caltech, and Stanford. This is a community observation, not a guarantee, and it reflects current conditions that may shift as female STEM participation grows. [D]

Consider a third micro-case. A family we'll call the Lees have a daughter in sixth grade at Harker who loves math and is qualifying for MATHCOUNTS state. The Lees assumed they were at a disadvantage — "everyone says being Asian is bad for admissions." After understanding the structural dynamics, they see it differently. Their daughter's profile (Asian, female, genuinely strong in competitive math) is actually distinctive at the intersection level, even if "Asian math student" is common at the category level. They also learn that the school-context effect means differentiation within Harker's applicant pool matters more than differentiation in the abstract. The Lees start thinking about how to deepen the math strength with research or mentorship, rather than broadening into more generic extracurriculars.

What This Chapter Is Not Saying

This chapter is not saying being Asian is a disadvantage in college admissions. The post-SFFA data shows Asian enrollment rising at most elite schools. The structural ceiling that existed under race-conscious admissions has been removed. The picture is more nuanced than the simple narrative in either direction.

This chapter is not saying you should choose a school based only on demographics. A school where your child thrives academically and socially is more valuable than demographic positioning. But ignoring demographics is like buying a house without checking the school district — you can do it, but you are leaving a major variable unexamined.

This chapter is not saying the system is fair or unfair. It is showing what the data says. The socioeconomic proxy system disadvantages affluent families of all races. Legacy preferences advantage families with multigenerational ties to specific institutions, which skews heavily white. The SFFA ruling removed one barrier and left others intact. Whether this net result is just depends on your values. What it means for your strategy depends on the data.

This chapter is not saying Asian students cannot get into top schools. They can and do — in large numbers. The question this chapter addresses is different: given the specific structure of Bay Area private school demographics, what does an Asian parent need to understand to make informed decisions? The answer is that school context, internal competition, and post-SFFA proxy systems are structural factors that shape outcomes in ways the brochure never mentions.

What This Means for Your Family

The emotional narrative around being Asian in college admissions runs hot — anxiety in every WeChat parent group, dire predictions at every dinner party. The structural reality is colder and more specific.

The race-based ceiling is gone. Harvard's Asian enrollment went from 30% to 41% in two years. This is real. If your child is applying to most elite schools after SFFA, they face less explicit racial balancing than applicants in 2022 did. This is a meaningful positive.

The socioeconomic floor was added. The new proxy-based diversity system provides no advantage to affluent private school families. This is a new structural factor that did not exist pre-SFFA, and it works against high-income Bay Area applicants regardless of race.

School context is the variable you control. Your child's demographic profile within their school matters more than their demographic profile nationally. At a school where 66% of applicants look like your kid, differentiation is harder. At a school where 24% do, it is easier. This is not a reason to transfer — but it is a reason to understand what you are working with.

Legacy is eroding. Stanford's legacy ban is permanent and structural. If other states follow California's lead, the largest remaining non-merit advantage in admissions will shrink. For Asian families without multigenerational Ivy connections, this is a tailwind.

Your child's application year is 2038. The legal landscape is actively contested. SFFA is threatening more schools. The Trump administration is pressuring universities on diversity essays. Additional state-level legacy bans are possible. No one can tell you what the rules will be in twelve years. What you can do is build genuine depth and distinction — which is the one strategy that works under every possible regulatory regime. [E]

Quick Reference

Factor	What the Data Shows	What It Means for You
Asian share varies 24-66% by school	Harker 66%, Crystal Springs 52%, Menlo 33%, SHP 24% (UC InfoCenter 2020-2024)	Your school choice determines how many similar-profile applicants your child competes against internally
Post-SFFA Asian % rose at most schools	Harvard 30→41%, MIT 40→47→38%, Stanford 41→44%	The race-based ceiling is gone; this is a structural positive
Duke Asian % declined	35%→29%→25% across two post-SFFA cycles	Not all schools moved in the same direction; school-level variation is large
Socioeconomic proxies replaced race	First-gen, Pell-eligible, geographic diversity now weighted	Provides zero boost to affluent Bay Area private school families
Stanford legacy ban (AB 1780)	Effective for students entering fall 2026+	Removes one of the largest structural advantages that disproportionately benefited non-Asian families
Legacy persists at Harvard/Yale/Princeton/Duke	11-14% of class; 5.7x admit rate advantage	The biggest remaining non-merit factor at these schools still does not help most Asian families
STEM-strong Asian female	Underrepresented at the intersection of gender and discipline	One of the few profiles where demographic dynamics work favorably for Asian applicants

****Figure 5.3:**** Decision framework for Asian families at Bay Area private schools. Start with your school's demographic composition, then consider where your child will apply.

Chapter Evidence Note

This chapter relies primarily on **Tier A** (official UC data), **Tier C** (institutional/journalistic reports), and **Tier E** (author synthesis) evidence.

Tier A claims: Asian share of UC applicants by school (Harker 66%, Crystal Springs 52%, Menlo 33%, SHP 24%, etc.) — from UC InfoCenter public data, 2020-2024. California AB 1780 (legacy ban) signed September 2024 — from Governor's office press release. These are verified official sources.

Tier C claims: Post-SFFA Asian enrollment percentages at Harvard, MIT, Columbia, Stanford, Yale, Princeton, and Duke — from campus newspapers (Harvard Crimson, The Tech, Columbia Spectator, Stanford Daily, Yale Daily News, Daily Princetonian, Duke Chronicle). Legacy admit rate advantage (5.7x) and ALDC composition (43% of white admits) — from SFFA v. Harvard trial record. Socioeconomic proxy strategies — from Inside Higher Ed, City Journal, and academic analyses.

Tier D claims: STEM-strong Asian female as a favorable intersection — from admissions consultant community consensus, not controlled studies.

Tier E claims: The interpretation that school demographic composition determines "internal competition," the framing of socioeconomic proxies as disadvantaging affluent Bay Area families specifically, the strategic advice on profile differentiation, and the overall synthesis connecting demographic data to admissions strategy — these are author judgment based on the Tier A and Tier C evidence above.

Before making school-choice or admissions-strategy decisions based on specific percentages, verify current data at the UC InfoCenter (ucinfocenter.universityofcalifornia.edu) and relevant university admissions pages. Post-SFFA policies and demographic trends are changing rapidly; the data in this chapter covers Classes of 2028-2029 and may not reflect conditions at the time your child applies.

Chapter 6: Private vs Public — Is It Worth It?

Who this chapter is for: T1/T2 readers — parents at any stage who are weighing whether \$50,000/year in private school tuition is justified by college placement outcomes. This is the chapter you read before writing the check or deciding not to.

The spine thesis of this book is that headline placement numbers hide critical structure. This chapter applies that principle to the question Bay Area parents lose the most sleep over: does private school actually improve your child's college outcomes enough to justify the cost? The answer is not yes or no. It is: it depends on which school, which child, and what you mean by "worth it." [E]

You are sitting across from your spouse at your kitchen island. Your daughter is in second grade. She is doing well — reading above grade level, enjoys math, has friends. You live in a strong public school district. You also live in a region where half the parents at her school are sending their kids to private middle school applications. The question is not whether your daughter is good enough for private school. The question is whether private school is good enough for your \$385,000.

That is the number. Seven years (grades 6-12) at approximately \$55,000 per year, after tuition increases. Before you spend it, you want to know what you are buying. This chapter tells you what the data shows — and what it cannot show.

The Headline Numbers: Private vs. Public

Here are the Ivy+ enrollment rates from Chapter 4, side by side:

School	Type	Class Size	Ivy+ Rate	Annual Tuition	Data Quality
Gunn	Public	447	~33.3%	\$0	D (user-collected)
Paly	Public	476	~21.0%	\$0	D (user-collected)
Menlo	Private	~143	~26.1%	~\$55K	A (3-yr rolling)
Castilleja	Private	51	21.6%+	~\$55K	A (1-yr, no counts)
Harker	Private	~260	~17.8%	~\$55K	A (3-yr combined)
Lynbrook	Public	472	~15.7%	\$0	D (user-collected)
SHP (non-athlete)	Private	~158	~10.5%	~\$55K	A (5-yr, decomposed)

If you stopped reading here, the conclusion would be absurd: Gunn, a free public school, has the highest Ivy+ rate of any school listed. Multiple private schools trail multiple public schools. Why would anyone pay \$55,000 per year for a lower placement rate?

The answer is that this table, as presented, is incomplete in ways that change the conclusion. But it is also not wrong. And the ways it is incomplete are themselves instructive. [E]

Why the Raw Numbers Are Misleading (In Both Directions)

Problem 1: The public school data is less reliable

The Gunn, Paly, and Lynbrook numbers come from user-collected spreadsheets — three-year averages, approximately 2021-2023, rounded. They have not been verified against official school publications. The private school numbers come from school-published documents (school profile PDFs, websites) and are generally more reliable. [D/A]

This matters. If the public school numbers are inflated by even a few percentage points — possible with user-collected data — the gap narrows or reverses. But the gap might also be accurate. We do not know, because public schools in California are not required to publish standardized college placement data. [E]

Problem 2: Class composition is not equivalent

Gunn and Paly draw from one of the wealthiest, most educated ZIP codes in America. The median household income in Palo Alto exceeds \$200,000. Most parents have graduate degrees. The baseline academic preparation, test prep access, college counseling investment (private counselors are common), and cultural expectation of elite college attendance is already extremely high. [D]

Gunn's 33.3% Ivy+ rate does not mean "a typical public school sends a third of its graduates to Ivy+ colleges." It means "a public school in one of the most educationally privileged communities in the country sends a third of its graduates to Ivy+ colleges." Comparing Gunn to a private school is comparing two highly selected populations. [E]

Problem 3: Athlete decomposition is missing everywhere except SHP

SHP's non-athlete Ivy+ rate is 10.5%. Its headline rate is 15.7%. The 5.2 percentage-point gap is entirely recruited athletes. No other school — public or private — publishes this decomposition. [A/E]

Private schools with strong athletic programs (SHP, Menlo, possibly Harker) likely have inflated headline rates. But public schools also have athletes who are recruited to Ivy+ colleges. Gunn and Paly have competitive water polo, swimming, and tennis programs. The athlete share of their Ivy+ numbers is unknown but nonzero. [E]

The honest answer: **on the data available, we cannot make a clean private-vs-public comparison.** What we can do is identify what private schools provide beyond placement rates, and let you assess which of those factors matter for your family. [E]

****Figure 6.1:**** The private school premium is not primarily about academics — it is about counseling ratio, recommendation letter quality, and peer group curation. The public school advantage is scale, diversity, and cost.

What Private Schools Actually Provide

1. Counseling Ratio

This is the most concrete advantage. At Menlo, two to three college counselors serve approximately 143 seniors — a ratio of roughly 1:50. At Harker, the ratio is similar. At Gunn, one or two counselors serve 447 seniors — a ratio of roughly 1:225. [A/D]

What does a 1:50 ratio buy you? A counselor who knows your child's name, story, and academic trajectory before junior year. Who can write a detailed institutional recommendation letter that speaks to specific accomplishments. Who can make strategic calls about Early Decision targets, which schools are likely "fits" versus "reaches," and how to sequence the application list. [D]

At 1:225, the counselor can provide logistics support — deadlines, transcript processing, basic list-building — but cannot know each student individually unless the student actively seeks them out. Most Paly and Gunn families supplement with private college counselors, at \$5,000-\$25,000 per engagement. [D]

A micro-case. A family we'll call the Tanakas have a son at Gunn. He is a strong student — 4.3 weighted GPA, 1540 SAT, co-captain of the debate team. The Tanakas hired a private college counselor for \$12,000. The counselor helped with school list, essay strategy, and application positioning. Their son got into Northwestern ED. The Tanakas estimate the private counselor provided roughly what a private school counselor would have provided as part of tuition — but at a

fraction of the cost. The other \$43,000/year in private school tuition buys other things: smaller classes, different peer group, different extracurricular access. Whether those things mattered more than seven years of savings — that is a values question, not a data question. [D/E]

2. Recommendation Letters

Private school teachers have smaller classes (12-18 students vs. 28-35 at public schools) and see the same students across multiple years in a smaller community. The resulting recommendation letters tend to be more specific, more personal, and more detailed. [D]

Admissions officers have told counselors — and counselors consistently report — that recommendation letters from well-known private schools carry implicit institutional credibility. A letter from a Menlo teacher or a Harker counselor arrives with context: the admissions office knows the school's rigor, grading standards, and student caliber. A letter from Gunn carries similar weight — Gunn is equally well-known to admissions offices — but the teacher at Gunn has 180 students and the teacher at Menlo has 60. The Menlo letter is likelier to include the kind of specific anecdote that admissions readers remember. [D]

3. Peer Group and Culture

The hardest thing to quantify and possibly the most important. Private schools select for families who prioritize education and can afford to pay for it. The resulting peer group is academically motivated by default. At Gunn and Paly, the honors and AP tracks create a similar peer group — but the student body as a whole spans a wider range. [E]

For some students, the wider range is an advantage: exposure to different backgrounds, interests, and socioeconomic realities. For others, the curated environment of a private school reduces distraction and normalizes high achievement. Neither is universally better. Both are real. [E]

4. Course Selection

Pinewood offers 17 AP courses. Nueva offers none (by design — they use their own advanced curriculum). Harker offers a broad AP catalog plus research opportunities. Gunn and Paly also offer extensive AP options and have the additional advantage of concurrent enrollment at Foothill College. [A]

The private school course advantage is not in the number of AP classes available — public schools match or exceed many private schools on that dimension. It is in the non-AP advanced options (independent research, college-level courses on campus, specialized seminars) and in class sizes small enough that every student gets substantive feedback. [D/E]

The Cost-Per-Ivy+-Admit Calculation

This is the number every parent calculates in their head, even if they know it is reductive. Let's make it explicit.

School	Ivy+ Rate	Ivy+ Admits/Year	Cost (6-12)	Cost per Ivy+ Admit
Gunn	~33.3%	~149	\$0	\$0
Paly	~21.0%	~100	\$0	\$0
Menlo	~26.1%	~37/yr	~\$385K	~\$10.4K per % point
Harker	~17.8%	~46/yr	~\$385K	~\$21.6K per % point
SHP (non-ath)	~10.5%	~17/yr	~\$385K	~\$36.7K per % point
Lynbrook	~15.7%	~74	\$0	\$0

Read this table carefully. The "cost per Ivy+ admit" is not what you pay to get your child into an Ivy+ school. It is the total tuition divided by the Ivy+ rate, giving you a rough sense of how much you are paying per percentage point of probability. And even this framing is misleading, because the private school rate includes factors (counseling, letters, peer group) that may causally contribute to placement, while the public school rate reflects community affluence, not school-added value. [E]

The honest calculation: if your child would attend Gunn or Paly without private school, and if the user-collected data is directionally accurate, the placement-rate argument for private school is weak. You are paying \$385,000 for a placement rate that may be lower than what you get for free. [E]

But "placement rate" is not the same as "placement probability for your specific child." The child who thrives in a 15-person seminar may underperform in a 35-person lecture. The child who needs close counselor relationships may flounder with a 1:225 ratio. The child who is a recruited athlete at a private school with a strong sports pipeline gets an advantage no public school can replicate. These are individual factors, not population-level statistics. [E]

****Figure 6.2:**** Decision framework for the private vs. public question. The answer depends on three factors: athletic recruitment potential, local public school quality, and individual child needs.

When Public Is the Better Choice

A micro-case. A family we'll call the Kims have a daughter who is self-motivated, socially confident, and academically strong. She does not need small classes to engage — she seeks out teachers on her own. She has a clear spike interest (computational biology) that she pursues through online courses and a summer internship she arranged herself. The Kims live in Palo Alto. They toured Menlo and Harker and liked both, but their daughter preferred the energy and diversity of Gunn. [D/E]

The Kims' calculation: Gunn's Ivy+ rate (~33.3%) is higher than any private school in the area. Their daughter's profile (self-directed, spike interest, strong test scores) would benefit from private counseling (\$15,000) but does not need the full private school wrapper. The \$370,000 they save goes into a 529 plan. Their daughter attends Gunn, works with a private counselor starting junior year, and applies to Stanford, MIT, and Princeton. [E]

This is not a hypothetical argument. The Palo Alto public schools produce more Ivy+ enrollees per year in absolute numbers than any single private school in this chapter. Gunn alone sends roughly 149 students to Ivy+ schools annually — more than every private school profiled combined. [D/E]

The public school advantage is strongest when:

- Your local public school is in the top tier (Gunn, Paly, or comparable)
 - Your child is self-motivated and does not need close institutional structure
 - You are willing to invest in private college counseling separately
 - Your child's spike interest does not require specialized resources only private schools offer
 - The \$350,000+ savings has a meaningful alternative use (529, home down payment, starting a business) [E]
-

When Private Is the Better Choice

A micro-case. A family we'll call the Mehtas have a son who is bright but needs external structure. In a large classroom, he fades to the middle — not because he cannot do the work, but because he does not assert himself. He had a transformative experience at a summer camp with 10 students per instructor: he led discussions, asked challenging questions, and was visibly more confident. The Mehtas recognize that their son performs best when someone knows him well enough to push him. [D/E]

The Mehtas' calculation: their son's academic potential is high but latent. The 15-student classroom at Menlo, the counselor who will know his name by sophomore year, the teacher who will write a recommendation letter based on three years of close observation — these are not luxuries. For this child, they are the mechanism by which potential becomes performance. The \$385,000 is not buying a higher Ivy+ rate. It is buying the environment in which their son is most likely to become the student who earns that rate. [E]

The private school advantage is strongest when:

- Your child needs small classes and close adult relationships to perform at their best
- Your child is a potential recruited athlete in a sport the school feeds to top colleges
- Your local public school is not in the top tier
- The school offers specialized programs (Nueva's design thinking, Harker's STEM research) that align with your child's interests
- You value the peer group curation and community aspects for their own sake, independent of placement outcomes [E]

The Lynbrook-Harker Comparison

This deserves its own section because the comparison is so direct. Lynbrook and Harker are both in San Jose. Both have majority-Asian student bodies. Both are academically intense. And their Ivy+ rates are remarkably close:

	Lynbrook	Harker
Type	Public	Private
Class size	472	~260
Ivy+ rate	~15.7%	~17.8%
Annual cost	\$0	~\$55,000
7-year cost	\$0	~\$385,000
Asian share of UC applicants	High (est.)	64%

The rate difference is approximately 2 percentage points. Over seven years of tuition, that 2-point premium costs roughly \$385,000, or \$192,500 per percentage point. [D/E]

A family choosing between Lynbrook and Harker is not choosing between a 15.7% chance and a 17.8% chance. They are choosing between two different educational experiences that happen to produce remarkably similar headline placement outcomes. The reasons to choose Harker over Lynbrook are real — smaller classes, dedicated counseling, STEM research infrastructure, campus facilities — but the placement-rate argument is not one of them. [E]

What This Chapter Is Not Saying

This chapter is not saying private school is a waste of money. The educational experience at a school like Menlo or Harker is genuinely different from Gunn or Lynbrook — different class sizes, different teacher-student ratios, different community feel. Many families value these differences for reasons unrelated to college placement.

This chapter is not saying public school is better. Gunn's high placement rate reflects the community it draws from, not necessarily the school's added value. A student who would thrive at Gunn might struggle at a weaker public school.

This chapter is not saying the data is definitive. The public school numbers are user-collected and unverified. The private school numbers hide athlete decomposition. Neither set of numbers tells you what would happen to your specific child in a different setting.

What this chapter is saying: **the ROI case for private school, measured purely by Ivy+ placement rates, is weaker than most parents assume.** The case for private school is real, but it rests on factors — counseling, relationships, environment, fit — that are harder to quantify than a placement percentage. If you are paying for the number, you may be overpaying. If you are paying for the experience, only you can assess whether it is worth it. [E]

Quick Reference

Question	Answer	Chapter reference
Does private school have a higher Ivy+ rate than public?	Not consistently. Gunn > every private school. Paly > most. Lynbrook ≈ Harker.	Ch. 4 comparison table
What does private school actually provide?	Counseling ratio (1:50 vs 1:225), recommendation quality, peer group, class size	This chapter
Can I replicate the private school advantage at public school?	Partially — private counselor (\$5-25K) covers the counseling gap	This chapter
When is private school clearly worth it?	Recruited athletes, children who need structure, weak local public schools	Decision framework above
When is public school clearly the better choice?	Self-motivated child + top-tier public school + willingness to invest in private counseling	Decision framework above
What about the \$385,000?	Opportunity cost: 529 plan, home equity, financial flexibility	Your family's values

****Figure 6.3:**** The private school premium in concrete terms. Both columns are real. The question is which column matters more for your child and your family.

Chapter Evidence Note

This chapter relies primarily on **Tier D** (user-collected public school data, community-reported counseling ratios) and **Tier E** (author synthesis and ROI calculations).

Tier A claims: Private school tuition ranges, class sizes, AP course counts, UC admissions data — from official school publications and UC InfoCenter.

Tier D claims: Public school Ivy+ enrollment rates (Gunn, Paly, Lynbrook) from user-collected spreadsheets, approximately 2021-2023 averages. Counseling ratios are from community knowledge and school staffing pages, not from controlled studies. College counselor cost ranges are from industry observation.

Tier E claims: The ROI calculations, the cost-per-percentage-point analysis, the decision framework, the assessment that Gunn's rate reflects community affluence rather than school-added value, and the judgment that the private school advantage rests more on counseling and environment than on placement rates — all author synthesis. The Lynbrook-Harker comparison is deliberately provocative and relies on the directional accuracy of the user-collected Lynbrook data.

Before making financial decisions based on these comparisons, verify current tuition rates with school admissions offices and placement rates with current school publications. Public school data should be cross-validated with Naviance or school-published data where available.

Chapter 7: Legacy, Early Decision, and Structural Advantages

Who this chapter is for: T2/T3 readers — parents who understand the placement data from earlier chapters and now want to understand the structural mechanisms that actually move admissions outcomes. This chapter goes beyond school-level data into the admissions system itself.

The first six chapters of this book decomposed what schools publish. This chapter looks at what colleges do — the institutional preferences that determine who gets in and why. Legacy. Early Decision. Recruited athletics. Dean's interest lists. These are the structural advantages that operate underneath the placement data. Most parents know they exist. Few understand how large they are, how they interact, and which ones a family can actually use. [E]

A family we'll call the Chens — you met them in Chapter 1 — have been doing their homework. They now understand that SHP's headline Ivy+ rate includes athletes, that Menlo's rolling three-year windows obscure trends, and that Gunn's free public school produces comparable or better placement rates. The Chens' daughter is in seventh grade. She is not an athlete. She is an excellent student with a growing interest in neuroscience. The Chens want to know: beyond grades, scores, and extracurriculars, what structural factors actually improve their daughter's chances? What can they influence, and what is baked into the system?

This chapter answers those questions with data. Some of the answers are uncomfortable.

The ALDC Advantage

In 2019, during the SFFA v. Harvard trial, internal Harvard admissions data became public for the first time. The data revealed what admissions consultants had long suspected: four categories of applicants — Athletes, Legacies, Dean's interest list (donors and VIPs), and Children of faculty (ALDC) — received a massive structural advantage. [B]

The numbers, from Harvard's own data: [B]

Category	Approximate Admit Rate	Compared to Overall (~5%)
Recruited athletes	~86%	17x
Legacies	~34%	7x
Dean's interest list	~42%	8x
Children of faculty	~47%	9x
Non-ALDC applicants	~4.7%	Baseline

Approximately 43% of white admits to Harvard had ALDC status. Approximately 15% of Asian admits did. The structural advantage was not distributed equally across racial groups. [B]

This data is from one school, covering classes admitted in the mid-2010s. But Harvard's admissions process is structurally similar to Yale, Princeton, Stanford, Duke, and other highly selective institutions. Admissions consultants who have worked with multiple elite schools consistently report that ALDC-type advantages exist across the Ivy+ tier, with varying magnitude. [B/D]

The SFFA ruling (June 2023) eliminated race-conscious admissions. It did not touch legacy, athletic, donor, or faculty preferences. These advantages remain fully operational at every Ivy+ school except those that have voluntarily eliminated legacy preferences — a short list. [A/B]

Legacy: What It Actually Means

The Distinction That Matters: Undergraduate vs. Graduate

Not all legacy is created equal. The critical distinction — one that most parents miss — is between undergraduate legacy and graduate legacy. [C/D]

Undergraduate legacy: At least one parent attended the college as an undergraduate. This is "primary legacy" at most schools and carries the strongest preference.

Graduate legacy: A parent attended the institution's graduate or professional schools (MBA, MD, JD, PhD) but not as an undergraduate. This is treated very differently across schools. [C]

School	Undergraduate Legacy	Graduate Legacy	Source
Harvard	Strong preference	Weaker; varies	Trial data [B]
Yale	Considered	Included in policy	Admissions consulting [C]
Stanford	Included — but banned from 2026 (AB 1780)	Same — banned	California law [A]
Princeton	Considered	Weaker preference	Admissions consulting [C]
Duke	Considered (guaranteed second review)	Policy not publicly defined	Research gap [C/D]

Duke is a critical case for many Bay Area families. Duke does not publicly state whether graduate degrees count as legacy. Multiple admissions consulting sources indicate graduate-only legacy is materially weaker than undergraduate legacy, but Duke has never confirmed this in public-facing materials. The Duke alumni admissions page refers to services for "alumni whose children or grandchildren are interested in applying" without specifying degree type. [A/C]

The bottom line for positioning: If both parents hold Duke MBAs but neither attended Duke as an undergraduate, their child's legacy status at Duke is ambiguous at best. Industry sources estimate the advantage, if any, is modest and not equivalent to primary (undergraduate) legacy. Do not build a strategy around graduate-only legacy as a primary differentiator. [C/E]

Legacy by the Numbers

The NYT/Opportunity Insights study (July 2023) analyzed admissions data across 12 elite colleges, including Duke. Key findings: [B]

- Legacy applicants had a **37% acceptance rate** vs. 9.5% for non-legacy applicants at the same institutions
- Legacy applicants in the **top 0.1% income bracket** were **seven times** more likely to be admitted than applicants with the same test scores
- **17%** of Duke's Class of 2027 survey respondents identified as legacy students

A 2011 study of 30 elite colleges found that "primary legacies" (one or both parents as undergraduate alumni) had a **45.1% increase** in acceptance chances on average. [C]

Legacy at Harvard represents 12-14% of each class. At Yale, approximately 11%. At Princeton, approximately 12%. These percentages have remained remarkably stable despite public pressure to eliminate legacy preferences. [B]

****Figure 7.1:**** The hierarchy of legacy preferences. Undergraduate legacy is the strongest; graduate-only legacy is substantially weaker and undefined at some schools (notably Duke).

Early Decision: The Biggest Lever Parents Can Pull

If legacy is the advantage you are born with, Early Decision is the advantage you choose. And the data suggests it may be the single most impactful strategic decision in the application process. [C/E]

ED vs. RD Rates

School	ED Admit Rate	Overall Admit Rate	ED Multiplier	Source
Duke (Class of 2030)	13.8%	~5.2%	2.7x	Duke Chronicle [A]
Duke (Class of 2029)	12.8%	~5.2%	2.5x	Duke Chronicle [A]

Duke's ED pool typically fills approximately 50% of the incoming class — roughly 847 students out of ~1,740 total. [A]

The ED advantage is not simply a higher admit rate. It reflects three interacting factors: [C/E]

- 1. Demonstrated interest.** ED is binding — the student commits to attend if accepted. Schools value this commitment because it improves their yield rate (the percentage of admitted students who enroll), which affects rankings.
- 2. Applicant self-selection.** Students who apply ED tend to be stronger applicants who have done their research and identified a clear first-choice school. The pool is, on average, more competitive than the RD pool.
- 3. Legacy concentration.** At Duke, 81.7% of legacy applicants applied ED, compared to 54.4% of all applicants (Class of 2025 data). Legacy advantage is concentrated in the ED round. Admissions consultants consistently state: "If a legacy student does not apply early, they give away any advantage they may have had." [C]

A micro-case. A family we'll call the Nguyens — you met them in Chapter 1 — have a daughter who is a strong fit for Duke. She has competitive math credentials, a genuine interest in Duke's biomedical engineering program (#3 nationally), and her father has a Duke MBA. The Nguyens face a strategic choice: apply ED to Duke, locking in the 13.8% admit rate and whatever legacy advantage a graduate degree provides — or apply RD to Duke alongside Stanford, MIT, and Princeton to keep options open. [A/C/E]

The data strongly favors ED. Duke's RD admit rate is approximately 3.7%. ED is 13.8%. That is a 3.7x multiplier. The graduate legacy advantage, if it exists, is most likely to operate in the ED pool where legacy applicants cluster. An RD application from a graduate-only legacy family is, statistically, nearly indistinguishable from a non-legacy application. [C/E]

The cost of ED: the Nguyens cannot compare financial aid offers from multiple schools. If Duke admits their daughter ED, they must attend regardless of the aid package. For families where financial aid is a decisive factor, ED is a constraint. For families where it is not, ED is the strongest strategic lever available. [E]

Stanford's Legacy Ban: AB 1780

On September 30, 2024, California Governor Gavin Newsom signed AB 1780, banning legacy and donor preferences at all California colleges and universities — public and private nonprofit — effective September 1, 2025. [A]

This is the single largest structural change in the admissions landscape for Bay Area families. Stanford, as a California private nonprofit, is now prohibited from considering legacy or donor status in admissions decisions for students entering fall 2026 onward. [A]

What this means in practice:

- **If your family has Stanford legacy:** That advantage no longer exists. Children of Stanford alumni (undergraduate or graduate) receive no preference in admissions starting with the Class of 2030.
- **If your family does NOT have Stanford legacy:** The playing field at Stanford just leveled. Slots previously allocated to legacy admits are now open to the general applicant pool.
- **If you are an Asian American applicant from a Bay Area private school:** This is the most significant structural improvement post-SFFA. Legacy preferences at Stanford historically benefited predominantly white applicants. Removing them opens space for applicants who compete on merit alone. [A/B/E]

The California law does not affect Harvard, Yale, Princeton, Duke, or any other out-of-state school. Legacy preferences remain fully operational at all Ivy League schools and most other elite private universities outside California. [A]

****Figure 7.2:**** California's AB 1780 eliminated legacy and donor preferences at Stanford (effective 2026). All other Ivy+ schools outside California retain legacy advantages unchanged.

The Post-SFFA Landscape: Who Gained, Who Lost

The June 2023 SFFA v. Harvard ruling eliminated race-conscious admissions. Two years of post-SFFA data now exist. The results are not what most people expected. [B]

Asian American Enrollment: School by School

School	Pre-SFFA (Class of 2027)	Class of 2028	Class of 2029	Net Change
Harvard	~29.9%	37%	41%	+11 pp
MIT	~40%	47%	38%	-2 to +7 pp
Stanford	~41%	41.3%	~44%	+3 pp
Yale	~24-25%	24%	30%	+5-6 pp
Princeton	~26%	23.8%	27.1%	+1 pp
Duke	~35%	29%	25%	-10 pp

Sources: Harvard Crimson, The Tech (MIT), Stanford Daily, Yale Daily News, Daily Princetonian, Duke Chronicle — all L2. [B]

The pattern is not linear. MIT surged to 47% Asian in the Class of 2028, then dropped to 38% in the Class of 2029. Yale fell, then recovered. Duke declined across both cycles. Harvard rose steadily. [B]

Pre-SFFA researchers had predicted average gains of less than 2 percentage points for Asian Americans nationally. The actual school-by-school variation far exceeds this — suggesting that normal statistical fluctuation may be as large as any SFFA effect. Two years of data is insufficient for definitive conclusions. [B/E]

The Compounded Disadvantage for Affluent Bay Area Families

The SFFA ruling removed race as a direct admissions factor. But it did not touch the structural advantages that disproportionately benefit white applicants: legacy, athletic recruitment, and donor preferences. [B]

Meanwhile, schools expanded socioeconomic proxies — first-generation college status, Pell eligibility, neighborhood disadvantage indices — to maintain diversity. These proxies systematically disadvantage affluent applicants of any race. [C]

For Asian American families at Bay Area private schools, the net effect is a compounded structural gap: [E]

1. **No race-based ceiling** (removed by SFFA) — a modest positive
2. **No socioeconomic boost** (affluent families get no proxy advantage) — neutral to negative
3. **Legacy/ALDC preferences continue** (disproportionately benefit white families) — ongoing negative
4. **Geographic diversity push** (Bay Area is overrepresented) — negative
5. **AB 1780** (Stanford legacy eliminated) — a concrete positive at Stanford only

The net calculation: SFFA was a marginal improvement for affluent Asian American families, not the transformation some expected. The largest remaining structural barriers — legacy and athletic recruitment — remain intact everywhere except Stanford. [B/C/E]

What SFFA Threatened but Didn't Touch

SFFA (Students for Fair Admissions) has continued to actively monitor and threaten schools post-ruling:

- **September 2024:** SFFA sent letters to Duke, Princeton, and Yale alleging continued race-consciousness in admissions, using the Asian enrollment drop at Duke (35% to 29%) as evidence. [B]
- **August 2025:** Duke and 31 other colleges were accused of antitrust violations through Early Decision programs (a separate legal theory from race). [B]
- Duke responded to neither allegation publicly. [B]

The legal environment is unsettled. SFFA is pushing for legacy elimination. The Trump administration DOE has pressured schools against using diversity essays as race proxies. Additional state-level legacy bans (following California's lead) are possible. The structural advantages described in this chapter may not be permanent — but they are current. [B/E]

What Parents Can and Cannot Control

****Figure 7.3:**** The structural advantages in admissions sorted by family controllability. The strongest lever most families can pull is Early Decision timing; the largest advantages (legacy, donor) are predetermined.

Factor	Can You Control It?	How Much Does It Matter?	What To Do
Legacy (undergraduate)	No — you attended or didn't	3-5x admit rate multiplier	If you have it, use it via ED
Legacy (graduate)	No	Modest to none	Don't build strategy around it
Early Decision	Yes	2.5-3.7x multiplier at Duke	Apply ED to top choice if finances allow
Recruited athletics	Partially — requires years of investment	~86% admit rate for Harvard recruits	Only viable if child is genuinely elite in a target sport
Donor status	Varies by wealth	Dean's list = ~42% at Harvard	Not actionable for most families
Spike / differentiation	Yes	Significant but unquantified	See Chapter 8
School choice	Yes	Affects counseling, recs, context	See Chapter 6
Application timing	Yes	ED >> RD for most schools	Apply ED unless financial aid comparison is essential

A micro-case. A family we'll call the Patels — you met them in Chapter 1 — have updated their mental model. The father attended IIT Bombay and has a Stanford MBA. The mother has a Columbia undergraduate degree. Their daughter, now in eighth grade, is exploring her application strategy six years in advance. The Patels now understand: the mother's Columbia undergraduate degree gives their daughter primary legacy at Columbia. The father's Stanford MBA gives nothing — AB 1780 eliminated even undergraduate legacy at Stanford. Their best structural play is Columbia ED, where the mother's undergraduate legacy combines with the ED multiplier. RD Columbia, without the ED boost, dissipates most of the legacy advantage. [A/C/E]

What This Chapter Is Not Saying

This chapter is not saying the admissions system is fair. The ALDC advantage is enormous and disproportionately benefits wealthy white families. That is what the data shows.

This chapter is not saying parents should game the system. Understanding structural advantages is not the same as endorsing them. Many of these advantages (legacy, donor status) cannot be manufactured. The ones that can be influenced (ED timing, school choice) are legitimate strategic decisions.

This chapter is not saying legacy will last forever. California has already banned it at Stanford. Federal legislation has been proposed. SFFA is pushing for elimination. The structural landscape a family plans around today may not exist when their child applies in 2035.

What this chapter is saying: **the admissions system operates on structural preferences that are larger than most parents realize, partially controllable, and in active flux.** The most important thing a family can do is understand which levers are available to them and make informed decisions — not assumed ones. [E]

Quick Reference

Structural Factor	Magnitude	Status (2026)	Bay Area Family Action
Legacy (undergrad)	3-5x admit rate	Active everywhere except Stanford	Apply ED to parent's alma mater
Legacy (graduate)	Modest to none	Ambiguous at most schools	Do not rely on as primary strategy
Early Decision	2.5-3.7x at Duke-type schools	Active, legally challenged	Apply ED to clear first choice
Athletic recruitment	~86% at Harvard	Active	Only if child is genuinely D1-caliber
Stanford legacy ban (AB 1780)	Eliminated	Effective 2026	Levels the field at Stanford
Post-SFFA Asian enrollment	+/- varies by school	Two years of data; volatile	Do not overreact to single-year swings
Socioeconomic proxies	Negative for affluent families	Expanding	Cannot be avoided; focus on controllable factors

Chapter Evidence Note

This chapter relies on a mix of **Tier A** (official school and government data), **Tier B** (peer-reviewed research and trial data), **Tier C** (admissions consulting reports), and **Tier E** (author synthesis).

Tier A claims: AB 1780 passage and effective date (Governor's press release), Duke ED application counts and admit rates (Duke Chronicle), Stanford and Duke class demographic data (university publications).

Tier B claims: Harvard ALDC admit rates (SFFA v. Harvard trial record), NYT/Opportunity Insights legacy study (37% vs. 9.5% legacy admit rates across 12 elite colleges), post-SFFA enrollment data by school (student newspapers citing official university data), pre-SFFA researcher predictions of <2 pp Asian American gains.

Tier C claims: Graduate vs. undergraduate legacy distinction (admissions consulting sources — Koppelman Group, CollegeVine, PrepScholar), Duke's 81.7% legacy-to-ED rate (Koppelman Group citing Class of 2025 data), Duke's guaranteed second review for legacy applicants (Koppelman Group), the 45.1% legacy advantage estimate from 2011 study of 30 elite colleges.

Tier E claims: The interpretation that SFFA was a marginal net improvement for affluent Asian American families, the "compounded disadvantage" framework, the recommendation to apply ED for legacy families, the Nguyens and Patels strategy cases, and the assessment that graduate legacy at Duke is "ambiguous at best."

The admissions landscape is in active legal flux. AB 1780 is settled California law. SFFA enforcement actions are ongoing. Legacy policies can change. Before building a multi-year strategy around any structural advantage, verify current policies with the specific institution.
